Auditors of Public Accounts, or, more strictly, 'Commissioners for auditing the Public Accounts,' are public officers, originally established by the 25 Geo. III. c. 52, in place of the patentees of the office of *auditors of the imprest* (Lord Sondes and Lord Cardiff), whose patents were vacated with compensation by that Act, and their functions and powers transferred to the commissioners above mentioned. The Queen is authorised by the stat. 46 Geo. III. c. 141, to appoint ten of these commissioners, who hold their offices during good behaviour, with salaries of 1500*l.* per annum to the chairman, and 1200*l.* per annum to the other commissioners. They are incapacitated from sitting in Parliament, and are sworn to execute the duties of their office faithfully and impartially. There is a provision in the statute, that no vacancy which may arise by death or otherwise in the number of commissioners after the first appointment shall be filled up without the express authority of Parliament, until the number is reduced to five, in which case the Queen may, from time to time, appoint new commissioners, so as to keep their numbers always to six. Two of the number are, by the 1 & 2 Geo. IV. c. 121, s. 17, empowered to examine parties on oath, and do all acts concerning the audit of public accounts.

By the 46 Geo. III. c. 141, s. 8, all public accountants are to transmit to the commissioners within three months after 31st December, or within three months of such day as the lords of the treasury shall order (see 2 & 3 Will. IV. c. 104), accounts duly attested, in manner pointed out by the Act, of all sums received and paid by them for the public service within the preceding year, together with proper vouchers for such receipts and payments, and a schedule of the same; which schedule is to be compared with the vouchers by an officer in the Audit-office. The commissioners may call on all public accountants, whenever they think fit, to account to them for the receipt, expenditure, or issue of all moneys or stores intrusted to them, and on failure they are to certify the defaulters' names to the remembrancer of the exchequer, and the attorney-general of England or Ireland, and lord-advocate of Scotland, in order that proceedings may be taken to compel them to account; unless, on the defaulter's application, the lords of the treasury think it proper to stay the proceedings for a reasonable time. By the stat. 1 & 2 Geo. IV. c. 121, it is enacted, that at the four quarter-days, the 5th day of January, 5th day of April, 5th day of July, and the 10th day of October, general imprest certificates shall be made out at the exchequer, specifying all moneys and exchequer bills issued at the receipt of the exchequer within the preceding quarter, and these certificates are transmitted to the commissioners of audit within thirty days after each quarter-day; and by the 10th section of 46 Geo. III. c. 141, the paymaster of the forces, the treasurers of the navy and ordnance, and all other public officers, who issue to any persons money for public services by way of imprest or on account, are required within three months after the 31st December in every year (or at shorter periods if ordered by the lords of the treasury, see 1 & 2 Geo. IV. c. 121, s. 6) to transmit to the commissioners of audit a certificate of such moneys, with the names of the persons to whom paid, and the commissioners are forthwith to take them into consideration. By the above-mentioned statute, 1 & 2 Geo. IV. c. 121, various regulations have been made respecting the mode of conducting the business of the commissioners of audit, by which the ancient and inconvenient system of keeping the public accounts has been superseded. The whole of the arrangements in the Audit-office are now subjected to the control of the lords of the treasury, who are authorised to make such orders and regulations for conducting the business of the office as they may think expedient, and best calculated to ensure the efficient discharge of the duties of the commissioners and other officers. By the 2 Will. IV. c. 26, the above commissioners are authorised to audit the accounts of receipt and expenditure of the colonial revenues; and the 2 & 3 Will. IV. c. 99, transfers the powers and functions of the commissioners of public accounts in Ireland to the commissioners for auditing the public accounts of Great Britain. By the 9 & 10 Vict. c. 92, the accounts of the receipt and expenditure of the naval and military departments are also referred to the Audit commissioners, whose reports thereon are to be laid before the House of Commons on the 31st of January and the 1st of June in each year.

AUGER. The auger is an instrument for boring holes in wood, larger than can be made with an awl or a gimlet. In its simple form, this instrument is too well known to need description. A few years ago a new kind of auger was invented, and introduced into some of our manufacturing establishments; it differs from the common auger in having a spiral like that of a corkscrew, which empties itself of the fragments of wood without having need to be withdrawn from the bore.

In 1854 an English patent was taken out by Mr. Ransom Cook, for an auger which had been patented in America a year and a half earlier. The construction had been suggested to him by a careful study of the mode of working adopted by certain insects. It consisted in giving to the lips or cutting edges of boring tools a curved or gouge shape at their extremities; also in the under-cutting or back-sloping of those edges, in order to give them a sliding or drawing movement in cutting. The improvement was very marked. In comparison with the common instruments, this auger possessed superior ease in boring holes through hard wood, at any angle with the fibres; the hole, too, is more truly cylindrical, and is produced without tearing or bruising the fibre.

AUGMENTATION, in old music, was an increasing of the value of the notes above their common and essential value. The term has long been known only to musical antiquaries.

AUGMENTATIONS, THE COURT OF, was established by 27 Hen. VIII. c. 27, for managing the revenues and possessions of all monasteries under 200*l.* a year (which by an act of the same session had been given to the king), and for determining suits relating thereto. It was called 'the Court of the Augmentations of the Revenues of the King's Crown,' and was a court of record with one great seal and one privy seal; the officers being a chancellor, who had the great seal, a treasurer, a king's attorney and solicitor, ten auditors, seventeen receivers, with clerk, usher, &c. All the dissolved monasteries under the above value, with some exceptions, were in survey of the court, the chancellor of which was directed to make a yearly report of their revenues to the king. The records of the Court are now at the Public Record Office, in the keeping of the Master of the Rolls (1 & 2 Vict. c. 94), and may be searched on payment of a fee.

AUGSBURG, CONFESSION OF. [CONFESSIONS.]

AUGUR. The earliest inhabitants of Italy, like all rude nations, imagined that they saw in every unusual occurrence a manifestation of the will of heaven. The power of interpreting the signs thus furnished by the gods was thought to depend upon a peculiar talent conferred upon the favoured mortal from his birth, but a certain discipline was necessary to give to the talent its full development. A superstition so deeply seated in the minds of the people was turned to account in the political constitution of Rome, by the establishment of a college of augurs, whose duty it was on all occasions of importance, whether of a public or private nature, by certain arts to ascertain and report the pleasure or displeasure of the gods. Romulus himself was said to have been skilled in the arts of divination from his earliest youth, and at the foundation of the city the claims of the rival brothers were decided by augury. The story of Tanaquil, of Servius Tullius, and still more the contest between the elder Tarquin and Attus Navius, afford additional evidence of the peculiar nature of this Roman superstition.

The institution of the college of augurs may be referred to the very earliest period of Roman history; for the assertion of Livy (i. 18, and iv. 4), that there were no augurs in the reign of Romulus is not merely opposed to the general tenor of the history of Rome, but directly contradicted by Cicero. ('De Republica,' ii. 9.) The original number of augurs is again differently reported. Cicero, himself an augur, says that Romulus associated three others with himself, and that Numa added two. (*Ibid.* 14.) Livy reports that in the opinion of the augurs of his time the number of the college was necessarily related to the number of the ancient tribes, and that consequently there must have been at the beginning either three or six; so that each of the three tribes should have either one or two augurs. On the other hand, the same author found it recorded in the annals of Rome that, prior to the Ogulnian law, there were but four members of the college. In these different accounts Niebuhr has pointed out strong reasons for giving the preference to the last. The notion of there having been three or six seems to have been a mere inference from the number of the tribes; and if all the tribes had stood on an equal footing, the argument would have had much weight. But the same writer has fully established the fact that the first two tribes possessed higher privileges than the third, and this in a more marked manner in the offices of a religious character, so that the number four, two for each of the privileged tribes, seems to point to a similar distinction in the highly-important powers of the augurate. On the other hand, though Cicero's evidence is in favour of the number six, his mode of accounting for that number is wholly at variance with the reasons of the augurs as reported by Livy. Again, if, as Cicero implies, Romulus was a member of the college, his successors in the regal power must have succeeded likewise to the augural office, a supposition in no respect confirmed by history, and scarcely compatible with what is reported of Tarquin's dispute with Attus Navius. Moreover, if such a power had passed through the hands of the kings, it remains to be asked what course was pursued at the change of the government from the regal to the consular form. At that revolution the political powers of the king devolved upon the consuls, or prætors as they were at first called, those of a religious character upon the priest, called *rex sacrificulus*; but there is no trace of evidence to show that the authority of the latter ever included the powers of the augurate. Under this view of the subject, Niebuhr is of opinion that originally the Ramnensian tribe possessing the chief powers of the state had its two augurs; that at a later period, when the Titienses were admitted to a share of these privileges, two others were added. This is confirmed by the statement of Cicero that Numa added two to the college, for the name of that king is always connected with the privileges of the second tribe. Livy, in his wish to reconcile the different accounts, has been driven to the supposition that when the Ogulnian law was brought forward, there may have been two vacancies by death; but it is not probable that the patricians would allow themselves to lose two seats in the college through such an accident, especially as even after the law was brought forward it was not too late for the remaining augurs to fill up the supposed vacancies—for in them the election resided. The Ogulnian law, which was brought forward by Q. and Cn. Ogulnius, and passed in the year B.C. 307, opened the pontifical and the augural colleges to the plebeians. (Liv. x. 6, 9.) In the latter, five plebeians were associated with the four patricians; and this number remained to the time of Sulla, B.C. 81, who increased it to fifteen. (Liv. 'Epit.' 89.) Lastly, among the many extraordinary powers conferred upon Augustus in B.C. 29 was the right of electing augurs at his pleasure, whether there was a vacancy or not; so that from that period the number of the college ceased to be definite. (Dion. xli. 20.)

But a more important point than the number of the augurs was the mode of election. At first, the augurs, like the other priests, were elected by the patrician assembly of the Curies, called the Comitia Curiata: but no election was complete without the sanction of the augury; so that the college possessed a virtual veto upon the admission of all members into it. (Dion. ii. 22.) This power was not unlikely to lead to a gradual usurpation of the elective right; and thus, as early as the year B.C. 452, we find it the practice of the college to fill up vacancies by co-optation as it was called, that is, by the votes of the existing augurs. (Liv. iii. 32.) This mode of election continued to the third consulship of Marius, B.C. 103, when the tribune Cn. Domitius Ahenobarbus carried a law, that in case of any vacancy in any of the sacred colleges, seventeen out of the thirty-five tribes chosen by lot should, by a majority of the votes of the said seventeen tribes, nominate a successor, whom the college should be bound to elect. (Cic. contra 'Leg. Agrar.' ii. 7, &c.) The return of Sulla to power restored the election to the colleges; but in the consulship of Cicero (B.C. 63) T. Attius Labienus, with the support of Cæsar, procured the reversal of Sulla's law. (Dion. xxxvii. 37.) After the death of Cæsar, Antony restored the old law, at least in the election of the chief pontiff, and therefore, most probably, in that of the other priests. (Dion. xliv. 53.) We have already mentioned that the emperors had the privilege of appointing augurs at their own discretion.

The ceremonies and superstitions which constituted the supposed science of the augurs would be tedious to enumerate; but that which especially characterised the augural office was the pretended power of ascertaining the divine will from the flights of birds. For this purpose the augur selected some elevated spot, on which he sat with his head veiled and his face turned towards some particular quarter of the heaven, varying perhaps according to the occasion; for the accounts differ so much that, while Livy says it was the east, we have the authority of Varro for the south, and Frontinus for the west. Then the augur, with a bent wand or crook, free from knots, called a lituus, marked off a certain portion of the heavens and of the earth, within which his observations were to be made, and again divided this portion into two parts—the right and left. The space so defined in the mind of the augur was called a *templum*, and the steadfast observation of the augur directed upon it may probably account for the meaning of the Latin word *con-templa-ri*, to contemplate, which has been adopted into our own language. The gods then signified their approbation by the appearance of birds on the left, and the augury was complete. For some purposes the whole circumference of the heavens, together with the corresponding parts of the earth, were divided, according to the rules of the art, by lines directed to the cardinal points, and others parallel to these. (Liv. i. 18, Dion. ii. 70, and the appendix to the translation of Niebuhr, vol. ii.) So prominent a place did the feathery creation hold as the interpreters of the divine will, that *av* or *avi*, the Latin for bird, is the chief element in the term *augur*, as it is also in the nearly equivalent word *auspex*. In the latter, the second syllable is deduced from *spec*, look, so that the word signifies bird-observer. The second element of the word augur does not admit of satisfactory explanation from any existing word in the Latin language. We have called the terms nearly equivalent, and if Plutarch's authority had been sufficient ('Romaica,' c. 72), we might have dropped the qualifying adverb. But a Roman antiquary would have pointed out many distinctions between them. The most important of these is, that the leading magistrates of Rome possessed the auspices (Cic. 'De Leg.' iii. 3) by virtue of their office, while the term augurium never refers to any other than an augur. The name auspex does not appear to have been in early times a technical word, and indeed was but rarely employed; but the derivatives from it were frequently used, and applied with considerable latitude to the augurs as well as to the magistrates. The objects of the auspices and auguries were nearly the same, and the means employed of a similar nature. Moreover, all legal disputes about the auspices of the magistrates seem to have been referred to the augurs. Under all these circumstances, we shall not attempt to draw a very nice line between them.

There were, as we have already stated, besides the movements of birds, a variety of other occurrences in the physical world which, as expressive of the will of heaven, came under the cognisance of the augurs. We shall not attempt to give a catalogue of all the forms which the superstitions of man may take; but absurd as these forms may have been, the political power of the augurs was most substantial. The election of a king, a consul, a dictator, a prætor, a curule ædile, of the various priests, pontifex, augur, vestal, flamen, &c., all were void unless the auspices were favourable. A general could not cross the pomœrium, or sacred boundary of Rome, the frontier of the state, or even a river, without the sanction of his birds. To engage an enemy in defiance of these interpreters of the will of heaven was sure to entail present or future defeat. In the assignment of public lands the science of the augur was required to mark out the different allotments. Among the patricians, the presence of an augur was necessary to render valid many of the proceedings of private life, as marriage and adoption; and the same political body found in the auspices a powerful argument against the rising claims of the plebeians. The auspices, they said, were their peculiar privilege, and as the leading magistrates could not fulfil their duties without such divine assistance, there was an insuperable bar to the election of plebeians. Of the three comitia, or legislative assemblies, that of the curies, being the special assembly of the patricians, was of course subject to the auspices; the same was the case with the mixed assembly of the centuries; but that of the tribes was free from such control. Of the two last (for the comitia curiata became obsolete) the assembly of the centuries was the most important, as possessing the election of the leading magistrate; and so complete was the veto of an augur in this assembly, that if he but heard a clap of thunder, nay, if he but said he had heard one, and that falsely, the proceedings of the assembly were void. Such was the power of the augural office; and it was strengthened by the law that a man once created an augur was an augur for life, no matter what crimes he might commit. (Plin., 'Ep.' iv. 8; Plutarch, 'Romaica,' 97.) On the pecuniary advantages of the office there are no very definite statements. That they received money in some shape from the public treasury is indeed positively stated (Dionys. ii. 6); and the poet Attius has made a bad pun at their expense, charging them with extracting *aurum* (gold) from the *aures* (ears) of those who believed in them; and the public money may perhaps be traced in the dinners given by the augurs on their election, which were celebrated in the annals of Roman gastronomy. (Cic., 'ad Fam.' vii. 16; Varro, 'R. R.' iii. 6; Plin., 'H. N.' x. 23.) In the latters years of the republic many of the duties of the augurs were performed in the most lax manner. At the inauguration of a magistrate, says Dionysius (ii. 6), speaking of his own time, the ceremony is a mere shadow of what it was. The candidate takes his seat, rises, repeats a set prayer in the open air, an augur then declares he hears thunder on the left, when in fact there was none, and the candidate forthwith enters upon his magistracy.

AUGUST. The month of August was originally called Sextilis, being the sixth month in the Alban or Latin calendar; and this name, as is stated, it retained in the calendars of Romulus, Numa Pompilius, and Julius Cæsar. Since Numa's reform, however, it has held only the eighth place in the series of months. In the Alban calendar, Sextilis consisted of twenty-eight days; in that of Romulus of thirty; Numa reduced the number to twenty-nine; Julius Cæsar restored it to thirty; and Augustus Cæsar, from whom it derived its new name of August, extended the number of days to thirty-one, which has continued ever since.

It was originally proposed that September should bear the name of Augustus, from the emperor having been born in that month; but he preferred Sextilis, not only as it stood next to July, which had been recently named after his predecessor Julius, but for the same reasons which influenced the decree of the Senate detailed by Macrobius, in his 'Saturnalia' (edit. Bipont. i. 261), viz., that since it was in this month that the Emperor Cæsar Augustus had entered upon his first consulship—had celebrated three triumphs in the city—had received the allegiance of the soldiers who occupied the Janiculum—had subdued Egypt, and put an end to civil war—it appeared that it was, and had been, propitious to the empire; and the Senate therefore ordained that Sextilis should thenceforward bear the name of Augustus.

Gassendi ('Kalend. Romanum,' apud Græv. viii. col. 164) says that Commodus wished to have had the month Sextilis called by his own name.

The Flemings and Germans have adopted the word August for Harvest; *Oogst maand* is the harvest-month. (Hadr. Junius 'de Annis et Mensibus,' apud Græv. Thesaur. viii. col. 217.) So the German *Augst-wagen*, a harvest-waggon (Wachter 'Glossar. German.'); and the Dutch *Oogsten*, to reap or gather corn from the field (Sewel's 'Dutch Diction.'). The Spaniards also have the verb *Agostàr*, to gather in harvest; and both French and Spaniards have phrases for making harvest, *faire l'Aoust*, and *hazer su Augusto*.

Our Anglo-Saxon ancestors named August Ƿeoꝺ monaꝺ, the weed-month, as abounding in noxious and useless herbs. ('Saxon Menolog.,' Lye's 'Saxon Dict.' in voce, and Bosworth's 'Anglo-Saxon and English Dictionary.')

Lammas Day, the first of the month, is also called the Gule of August (Brand's 'Popular Antiq.' i. 275), probably from the Gothic HIOL or IUL, a *wheel*, indicating that revolution of season which brought the return of harvest. This day, called by our Anglo-Saxon ancestors Hlaþ-mæſſe, that is, loaf mass, was the feast of thanksgiving for the first fruits of the corn.

(Compare Pitisci 'Lexicon Antiq., Græc. et Roman.,' v. Augustus; the different treatises printed in Grævius's 'Collection;' and Brady's 'Clavis Calendaria,' i. 76.)

AUGUSTINE (ST.), CANONS OF THE ORDER OF, usually called AUSTIN CANONS. Regular Canons, says Bishop Tanner (Pref. to 'Notit. Monast.'), were such as lived under some rule; they were a less strict sort of religious than the monks, but lived together under one roof, had a common dormitory and refectory, and were obliged to observe the statutes of their order.

The chief rule for these canons was that of St. Augustine, who was made Bishop of Hippo, A.D. 395. But they were little known till the 10th or 11th century, were not brought into England till after the Conquest, and appear not to have obtained the name of Augustine or Austin Canons till some years after. (Bingham, 'Antiq. of the Christ. Church,' b. vii. c. 2. s. 9.)

Bale ('Script.' cent. xiii. 4) and Sir Robert Atkyns ('Antiq. of Glouc.') say, that these canons were brought into England by St. Birinus in the beginning of the 7th century; A.D. 630 or 640, as Fuller, quoting the 'Chronicon Augustin' of Joseph Pamphilus, states in his 'Church History (b. vi.); but those were certainly secular canons whom he placed at Dorchester in Oxfordshire; and all other historians agree that we had no regular canons here till the 11th, or probably till the 12th century. For though they differ about the place of their first settlement, yet the general opinion is, that they came in after king Henry I. began his reign. Jos. Pamphilus, according to Fuller ('Ch. Hist.' ut supr.), says they were seated in London, in 1059; but this is not believed. Somner says that St. Gregory's in Canterbury, which was built by archbishop Lanfranc in 1084, was their first house ('Antiq. Canterb.'); but Leland's saying ('Collectan.' vol. i.) that Archbishop Lanfranc placed secular canons at St. Gregory's, and that Archbishop Corboyl changed them into regulars, makes the authority of that judicious antiquary in this case doubtful. Reyner says ('Apostol. Benedict.' tr. i.) that they were first brought into England by Athelwulphus or Adulphus, confessor to king Henry I., and had their first house at Nostell in Yorkshire; but they seem not to have been settled there till Thurstan was archbishop of York, and that was not till 1114. Thurstan was elected in 1114, but not consecrated till 1119. (Willis's 'Cathedrals,' vol. i.) Stow ('Surv. of London') mentions that a gift of lands was made to Norman, the prior, and to the canons of the Holy Trinity, or Christ Church within Aldgate, London, in 1115, but he does not say that it was the first establishment of the order, and that house was not built till R. Beaumeis was bishop of London; whereas the house of these canons at Colchester was founded before the death of Bishop Maurice his predecessor, which happened Sept. 26, 1107. (Godwin 'de Præsul;' Newc. 'Rep. Eccl.' vol. i.) And therefore Bishop Tanner thinks that John Rosse ('Mon. Angl.' vol. vi.) and Pope Paschal II. (Ibid.) are right in placing them first at Colchester, though it could not be in Rosse's year, 1109, but was rather in 1105, in which Fuller ('Ch. Hist.' b. vi., s. i., c. 6.) places the coming of these canons into England.

Stevens tells us, in his Continuation of Dugdale (vol. ii.), that though there were regular canons who embraced the rule of St. Austin, taken from his 109th epistle, in the 11th century (as particularly at the Abbey of St. Denis, at Rheims, about 1067), yet the regular canons did not make solemn vows till the 12th century; and did not, in general, take the name of "regular canons of St. Austin" till Pope Innocent II. ordained, in the Lateran Council, in 1139, that all regular canons should submit to that rule of St. Austin in his 109th epistle. So that these regular canons certainly fall short of the time of their pretended founder; and therefore when black or regular canons are mentioned before 1105, the reader must thereby understand secular canons; for it was usual in those days to call the secular canons of cathedral and collegiate churches "canonici regulares," to distinguish them from the common parochial clergy, though probably many of those societies might become Austin canons afterwards. In 1244, the rules were sanctioned by a bull from Pope Innocent IV., and in 1532 the 'Barefooted Augustines,' a sort of reformed order, was established.

Their habit was a long black cassock, with a white rochet over it, and over that a black cloak and hood. The monks were always shaved, but these canons wore beards, and caps on their heads.

The nuns of the order were probably the elder of the two, as there certainly was a society of females who lived apart under the spiritual direction of the Bishop of Hippo himself; and a cloister was founded at Venice in 1177 by Pope Alexander III.; these wore black garments, which in 1632 were changed to violet.

Tanner says he found above 175 houses of these canons and canonesses in England and Wales.

By the rules of the order, among many other ordinances, the vows of chastity and poverty were to be taken by all persons joining the order, to which all property whatever was to be relinquished by the individual; alms might be solicited; on any business requiring members of the fraternity out of the house, two were always to be sent together; concord and implicit obedience were inculcated; and talking was forbidden. Of the habit, it was only directed that it should not be conspicuous.

The separate societies in England and on the Continent were extremely numerous, and many, no doubt, were marked by some peculiarity; but the four great branches which sprung from the parent root were the Præmonstratensians, Trinitarians, Dominicans, and the Knights Hospitallers, with more or less of variation according to circumstances.

Copies of the rule of the Augustine order will be found among the Harleian manuscripts in the British Museum, Numbers 2939, 3392, 3995, and 4053. Wilkins, in his 'Concilia,' vol. ii., and Spelman, 'Concil.' vol. ii., have given the Constitutions of Pope Boniface XII. for the reformation of this order in 1339; and the Cottonian Manuscript, Vespasian D. I. contains, 1. The proceedings at various general and provincial chapters of the Order, held within the province of

Canterbury from 1325 to 1404, fol. 41, b. : 2. The details of the great chapter held at Leicester in 1518, fol. 63. This last chapter was held preparatory to the promulgation of the reformed rules of the order for the houses in England, set forth by Cardinal Wolsey in the following year. The cardinal's regulations are preserved in the Cottonian Manuscript, Vesp. F. IX. 'Ordinationes et Statuta per Thomam Wolsey, titulo S. Ceciliæ Cardinalem, per singula Monasteria Canonicorum Regularium S. Augustini observanda: composita xxij° Martii, A°. Dom. MDXIX. et Regis Henrici Octavi xj.'

AULIC COUNCIL (Reichshofrath), was the title of the second chamber or tribunal under the old German empire, the first being the Imperial chamber or Reichskammergericht, which was the supreme tribunal of the German empire. [IMPERIAL CHAMBER.] It was instituted by the Emperor Maximilian in 1501, originally as a personal council for the sovereign, but it soon acquired a jurisdiction over a variety of affairs. The Aulic Council consisted of a president, a vice-president, the vice-chancellor of the empire, and eighteen councillors, six of whom were required to be protestants: the votes of these six, when unanimous, were considered equal to those of all the rest. The nomination of the Aulic Councillors belonged to the emperor, who paid them, with the exception of the vice-president, who was appointed by the archbishop of Mainz; they were drawn from two classes, nobles and civilians. The affairs which were under the exclusive jurisdiction of this court were of three sorts: 1. Feudal processes concerning the immediate feudatories of the emperor; 2. Those called *reservata Cæsaris*, including appeals from the hereditary dominions of the emperor; 3. All matters concerning the imperial jurisdiction in Italy, as the emperor was styled King of the Romans. The investitures of counties of the German empire were given by the Aulic Council. The Aulic Council did not interfere in the political or state affairs of the empire. The council ceased at the death of every emperor; and the new emperor made a fresh appointment. The decisions of the Aulic Council were submitted to the emperor for his approbation, by which they became law. Pöllnitz, in the first volume of his 'Memoirs,' compares the Aulic Council to the old French Parliament, with this difference, that the former could not make remonstrances to the sovereign, and did not register any other acts but its own decisions.

At the extinction of the German empire by the renunciation of Francis II. in 1806, and the establishment of the Confederation of the Rhine under the protection of the Emperor Napoleon, the Aulic Council ceased to exist. There is, however, a council at Vienna for the affairs of the war department of the Austrian empire: it is called *Hofkriegsrath*, of which the president possesses the powers of a minister of war, subject of course to the will and directions of the sovereign.

AURANTIIN. [HESPERIDIN.]

AURATES. [GOLD.]

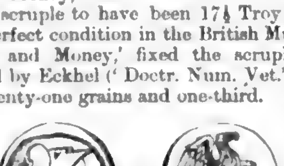
AUREOLE. [NIMBUS.]

AU'REUS, or DENARIUS AUREUS, the ordinary Roman coin of gold, was equivalent to twenty-five silver denarii, or a hundred sestertii.

Gold was first struck at Rome in the year of the city 547, or 207 before Christ, in the consulship of C. Cl. Nero and M. Liv. Salinator, sixty-two years after the introduction of the coinage of silver. The earliest coin of gold at this time was named a scruple (scrupulum), and

Scrupulum.
Brit. Mus. Gold. Actual size.

went for twenty sesterces of that age. (Plin. 'Nat. Hist.' lib. xxxiii. c. 3; edit. Dalecampii, et Variorum. In other editions, c. 13.) It had the head of Mars on one side, and an eagle standing on a thunderbolt upon the other, with the word 'ROMA' below; and was marked XX at the back of the head of Mars. Raper ('Inquiry into the value of ancient Greek and Roman Money, Philos. Transact.' lxi. p. 508,) determines the weight of the scruple to have been 17¼ Troy grains, which is the weight of one in perfect condition in the British Museum; but Hussey 'Ancient Weights and Money,' fixed the scruple at 18·06 grains. Nauzeus, as quoted by Eckhel ('Doctr. Num. Vet.' tom. v. c. 4), makes the true weight twenty-one grains and one-third. These, as it appears,



A triple Scrupulum.
Brit. Mus. Gold. Actual size.

are Paris grains (Eckhel, v. 4); 17¼ Troy grains being about equivalent to 21⅓ Paris grains. Its double was marked XXXX, or forty sesterces; and its triple ⊥X, or sixty, which weighed 52 grains. The symbol which precedes the X on this triple scruple, indicates L or 50: Eckhel shows, that on the denarii of Tib. Claudius, and in other cases, the Romans represented 50 by a symbol very like an inverted T. The aurei preceding the empire were heavier than they were afterwards. Mr. Hussey states the weight of that of Sulla as 130·1 grains, but had seen none heavier than one of Pompey, which weighed 128·2 grains; and Mr. Noel Humphreys says the Aureus of Lucullus weighed 206 grains, while he had seen none weighing more than 167 grains.

Pliny proceeds to say that it was afterwards usual to coin forty pieces out of the pound of gold (larger in size, of course), bearing the general name of Aurei, and that the Roman emperors by degrees made them forty-five to the pound. In a passage, the corruptness of which is more than suspected, some of the texts ascribe this last change to Nero.

Alexander Severus coined pieces of one-half and one-third of the aureus, called *Semissis* and *Tremissis* (Æl. Lamprid. in 'Alex. Severi Vita,' c. 39), whence the aureus came to be called *solidus* or *solidus aureus*, as being the integer.

Soon after the reign of this prince the coinage became very irregular, till Constantine entirely new-modelled it by coining aurei of seventy-two to the pound of gold ('Codex Theod. de Ponderatoribus,' § 1. 'Cod. Justin.' l. x. tit. 70, de Susceptoribus, § 5); a more convenient number than either forty or forty-five, as it divided the ounce and half ounce without a fraction.

Eckhel ('Doctr. Num. Vet.' ut supr.) divides the variations of weight of the aurei between the year 547 of Rome and Caracalla's time into eight epochs, varying in the respective coins from 153 to 128 (Paris) grains. That the estimates are correct may be gathered from the following facts, ascertained from aurei, or gold denarii, all in a state of high preservation in the British Museum. An aureus of Julius Cæsar weighed 123 grains, which is exactly the weight of an English sovereign. Out of twenty-five gold denarii of Augustus, one weighed 115 grains, five weighed 120 grains each, three 120½, four 121 grains, four 122, and one 127. In Meyer's 'Grosse Conversations Lexikon,' mention is made of an aureus of Augustus, found at Herculaneum, weighing 540 grains, of which a representation has been published by Kehl; and one of Valens, now in the Vienna cabinet, still heavier. Mr. Noel Humphreys calls the first a medallion, and the second is no doubt of a similar character. Of fifteen aurei of Nero, four weighed 113 grains, two 114, two 116, two 118, one 119, one 120. An aureus of Maximianus II. weighed 81 grains, Carausius 67, and Maxentius 79. The coin of Carausius, of which a copy is here given, is believed to be unique. The

Brit. Mus. Gold. Actual size.

Rev. Mr. Cracherode, who bequeathed it to the British Museum, bought it at the price of 150*l*. Of the aurei of Constantine in the Museum, one weighed 66 grains, three 67, three 69½, one 73½, and one 81½. The highest weights are possibly of coins struck before Constantine's re-arrangement of the coinage. All here mentioned, as far as can be ascertained, are of gold without alloy. The town of Cæsarea possessed a mint at one time as well as Rome; and there is no doubt there were also many fraudulent aurei. Macrobius states ('Sat.' 552) that a Jewish coin of precisely the same value as an aureus was in his time current at Ephesus.

The average weight of the aurei of Augustus, then, appears to have been nearly 121 grains; that of Nero's aurei nearly 117.

Raper says the Consular aurei weighed at a mean 126 grains. Some of the Family aurei in the Museum weigh 122, 124, and 125 grains.

The following is Letronne's table of the mean weight of Aurei, transferred into Troy grains:—

	French gr.	Troy gr.
J. Cæsar	153·25	125·73
Augustus	148·71	121·97
Tiberius	145·7	119·53
Caligula	144·5	118·55
Claudius	144·6	118·63
Nero	139·5	114·44
Titus	137·3	112·64

(Letronne, 'Considérations générales sur l'Evaluation des Monnaies Grecques et Romaines,' &c. 4to. Paris, 1817.)

Victors in the chariot races were usually rewarded with aurei. (Suetonius, 'Claud.' cap. 21, § 10; Juv. 'Sat.' vii. 243.) The Scholiast observes that no more than five were allowed to be given in such cases. (Buleng. 'de Circo,' c. 55.) The fee (probably the maximum) to a lawyer was *centum aurei*, see Ulpian (D. i. 12, 'de extr. cognit.') A single aureus was all that Justinian permitted to be risked at dice. (Cœl. Calcagninus 'de Talorum Tess. et Calc. Ludis,' ap. Græv. 'Thesaur,' tom. vii. col. 1228.)

The reader who wishes for information upon the aureus beyond what is here given, may consult Pitiscus, 'Lexicon' i. *in voce*; Eckhel, 'Doctr. Num. Vet.' tom. v.; Pinkerton, 'Essay on Medals,' vol. i.; Raper's 'Inquiry,' already referred to; Böckh's 'Untersuchungen über

Gewichte, Münzfüsse, und Masse des Alterthums in ihrem zusammenhange,' Berlin, 1838; Hussey, 'Ancient Weights and Money,' and H. Noel Humphrey, 'Coin Collector's Guide.'

AURIC ACID. [GOLD.]

AURI'GA, the Charioteer, a constellation situated between Perseus and Gemini. It is represented as a man holding a bridle in the right hand and supporting a goat and kids on the left arm. The star in the body of the goat, called Capella (and Alioth by the Arabs) is of the first magnitude, and presents the best guide to the constellation. There is no satisfactory account of the mythology of this figure. It is said to have been the Horus of the Egyptians; among the Greeks, the human figure is by different writers called Erichthonius, Bellerophon, Hippolytus, &c.; while the goat is Amalthæa, the foster-mother of Jupiter. But this explanation is even more unsatisfactory than most others, owing to the want of apparent connection between the figures of the group.

The following are the principal stars in this constellation :—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
ι	3	1520	4
ε	7	1540	4
ζ	8	1541	4
α	13	1613	1
δ	33	1885	3·5
β	34	1895	2
θ	37	1900	4
κ	44	2001	4

AURIPIGMENTUM. [ARSENIC, TERSULPHIDE OF.]

AUROCYANIDES. [GOLD.]

AUROHYDROCYANIC ACID. [GOLD.]

AURORA. [EOS.]

AURORA BOREALIS. [POLAR LIGHTS.]

AUSCULTATION, from *ausculto* to listen, the method of distinguishing the states of health and disease by the study of the sounds produced by the organs in the movements which they make in the performance of their functions. When air rushes by the wind-pipe into the lung in the action of inspiration; when it is expelled through the same tube in the action of expiration; when it is acted upon in the larynx by the organs of the voice; when the heart beats, that is, when the different chambers of which it is composed forcibly contract; when the blood flows through the great arterial trunks; when air is contained in the intestines and is acted on by these organs in their natural movements,—in all these cases sounds are produced which can be heard, often by the unassisted ear; and still more distinctly by the aid of an acoustic instrument. When attention is paid to these sounds, it is found that they differ greatly from each other. The sound of the air in the wind-pipe during inspiration is different from that in the same tube in expiration; the sound of the air in the larynx during the act of speaking is different from both; while the sound produced by the action of the heart, and even by the action of its different chambers, may be discriminated the one from the other. By the study of these sounds, it is obvious that it may be possible to become acquainted with those which are natural to the different organs in the state of health: but when these organs become disordered, their movements are modified in a great variety of modes, each modification of movement being attended with a corresponding modification of sound; consequently, these modified sounds are capable of affording indications of various states of disease, the difference between the healthy and the morbid sound being the sign and the measure of the deviation of the organ from the state of health. The physician, carefully studying the sounds produced by the organs during life, makes himself familiar with those which are natural to them: in a particular case he hears sounds which he knows to be altogether different from those that are natural: the patient dies; the physician examines the organs after death; he finds that a certain organ is diseased in a certain mode; this morbid condition of the organ, which he has been taught by inspection after death, he associates in his mind with the peculiar sound which he observed that the organ emitted during life. Another case, attended with the same sound, is proved by inspection after death to be connected with the same disease of the same organ: and every time that he hears this peculiar sound, he finds the same organ diseased in the same mode. A peculiar sound may thus become the sure and certain indication of a particular disease; in this manner, by persevering attention during life and careful examination after death, it may be possible to discriminate the morbid states of all the organs that give, when in action, a distinguishable sound. Extended and repeated observation has shown that the detection and discrimination of disease by this mode may be effected with a minuteness and precision that could not possibly have been credited previous to the practical demonstration of the fact; and modern science has elicited, and almost matured, a new mode, an *inventum novum*, as one of the first suggestors of the method justly termed it, of discovering the morbid states of several of the most important organs of the body.

To the philosophical mind nothing is more interesting and instructive than to trace the history of useful discovery. It is clear that the idea on which the modern art of auscultation is founded, had occurred to Hippocrates upwards of two thousand years ago. "You will know by this," says this first recorded observer of disease as denoted by sound, "that the chest contains water and not pus, if, on applying the ear for a certain time to the side, you hear a sound like that of boiling vinegar." The non-existence of dissection in the age and country of Hippocrates prevented all accurate and extended observation; and consequently rendered it impossible to follow out to any sure and useful result the idea which had occurred to the most ancient writer on physic. Accordingly, the suggestion of Hippocrates seems to have attracted no attention for many centuries, and the mode of studying disease founded upon it, if it had ever been carried to any extent in remote ages, had long sunk into oblivion.

About the middle of the 17th century, a distinguished philosopher and mathematician, who was not of the medical profession, and who does not appear to have been acquainted with the writings of Hippocrates, had the penetration to see that advantage might be taken of the sounds produced by the motions of the internal organs to discover the nature of their diseased states, and he even predicted that artificial means would some day be employed to assist the ear in the pursuit of that object. "There may be a possibility," says Hooke, in his posthumous works, "of discovering the internal motions and actions of bodies by the sound they make. Who knows but that, as in a watch, we may hear the beating of the balance, and the running of the wheels, and the striking of the hammers, and the grating of the teeth, and multitudes of other noises;—who knows, I say, but that it may be possible to discover the motions of internal parts of bodies, whether animal, vegetable, or mineral, by the sounds they make: that one may discover the works performed in the several offices and shops of a man's body, and thereby discover what engine is out of order,—what works are going on at several times, and lie still at others, and the like. I have this encouragement not to think all these things utterly impossible, though never so much derided by the generality of men, and never so seemingly mad, foolish, and fantastic; that, as the thinking them impossible cannot much improve my knowledge, so the believing them possible may perhaps be an occasion for taking notice of such things as another would pass by without regard as useless. And somewhat more of encouragement I have also from experience, that I have been able to hear very plainly the beating of a man's heart; and it is common to hear the motion of the wind to and fro in the guts and other small vessels: the stopping in the lungs is easily discovered by the wheezing. As to the motion of the parts one amongst another, to their becoming sensible, they require either that their motions be increased, or that the organ be made more nice and powerful to sensate and distinguish them as they are; for the doing of both which I think it is not impossible but that in many cases there may be helps found."

This prediction has been realised: helps have been found. About a century after this passage was written, Leopold Avenbrugger, a German physician then residing at Vienna, fell upon an artificial method of producing sounds in various regions of the body [PERCUSSION; AVENBRUGGER, BIOG. DIV.] by which the physician might judge of the state of the subjacent parts. This method, announced to the world in a small volume in Latin, first published in the year 1761, attracted little attention either among the countrymen of the inventor or among foreign nations for the space of half a century. It was translated into French by Rozière in 1770. In the year 1808, the celebrated Corvisart again translated it, and made his method known to all the countries of Europe. From that period the practice of percussion has been pretty general, and it soon became attended, in skilful hands, with results far more precise and certain than had been anticipated.

The attention of physicians having been thus distinctly directed to the method of studying disease from sounds produced in the body whether naturally or artificially, a number of young French physicians, disciples of Corvisart, about the commencement of the present century, took up the subject with extraordinary zeal. Among the most distinguished of these young men were MM. Double, Bayle, and Laennec. Speaking of the signs furnished by respiration, and of the sounds produced by it within the chest, M. Double, in his work on Semeiology, published two years before the discovery which led to the establishment of auscultation as an art and science, says, "In order to hear distinctly the sounds within the chest, we must apply the ear closely to every point of all its aspects, by which means we can distinguish not merely the kind and degree of the sound, but even its precise site. I have frequently derived great benefit from this mode of investigation, to which I was naturally led by the employment of the like method in exploring the pulsation of the heart."

At the very time when this was written, Laennec and several of his fellow-pupils, under the guidance of their master, Corvisart, while diligently studying chest diseases by means of percussion, met occasionally with cases in which this method afforded them little or no assistance; and in the hope of obtaining further aid, they accustomed themselves in such cases to apply the ear closely to the chest. Little practical benefit resulted for some time: but at length it led to a discovery of inestimable advantage; a discovery which may be said to have enabled the physician to see into the chest almost with as much clearness as if its walls were transparent. The following is the account of this discovery in the words of the remarkable man who made it, and who in the course of a few years, with a diligence scarcely ever exceeded, developed, matured, and systematised the highly-important practical results which it has afforded.

"In the year 1816," says Laennec in his great work 'De l'Auscultation Médiate et des Maladies des Poumons et du Cœur,' "I was consulted by a young woman affected with the general symptoms of diseased heart, and in whose case percussion and the application of the hand were of little avail, owing to her being extremely lusty. The immediate application of the ear being inadmissible for obvious reasons, I happened to recollect a simple and well-known fact in acoustics, and fancied it might be turned to some use on the present occasion. The fact I allude to is the great distinctness with which we hear the scratch of a pin at one end of a piece of wood on applying our ear to the other. Immediately on this suggestion, I rolled a quire of paper into a kind of cylinder, and applied one end of it to my patient's chest and the other to my ear, and was not a little surprised and pleased to find that I could thereby perceive the action of the heart in a manner much more clear and distinct than I had ever been able to do by the immediate application of the ear. From this moment I imagined that means might be found to ascertain the character, not merely of the action of the heart, but of every species of sound produced by the motion of all the organs within the chest."

Diligently applying himself to improve and perfect the rude instruments which he employed in his first trials, Laennec at length constructed that which is now in general use, called the Stethoscope (from στῆθος, *breast* or *chest*, and σκοπέω, *to examine* or *explore*), by the aid of which he was at once impressed with the conviction that he should be enabled to discover "a set of new signs of diseases of the chest, simple and certain, and such as might probably render the diagnosis of these diseases as positive and circumstantial as that of many affections which come within the immediate reach of the hand or the instrument of the surgeon." And this conviction, to a great extent, has been realised, for a new, clear, steady, and certain light has, by the aid of this instrument, been thrown on almost all the diseases of all the organs contained in the chest.

The art of distinguishing disease by sound comprehends then two distinct methods, that of *auscultation* and that of *percussion*. The study of auscultation may be pursued either by the unassisted ear, or through the medium of instruments; the first is called immediate or direct, the second mediate auscultation. In like manner percussion may be performed either on the natural surface of the body, or through the medium of some solid or tense substance firmly applied to it. The first is termed direct, the second mediate, percussion. [PERCUSSION.] See also Double, 'Séméiologie Générale;' Forbes's Translation of Corvisart's 'Avenbrugger;' Laennec, 'De l'Auscultation Médiate;' arts. 'Auscultation,' in 'Cyclopædia of Practical Medicine,' and in the 'Dictionary of Practical Medicine,' by Dr. Copland.

AUSONIANS (AU'SONES), an ancient people of the Italian peninsula, who appear to have been a branch of the great Opican or Oscan nation, originally settled in Bruttium, and thence driven by the Œretri into Campania. They were either an identical or nearly related people with the Aurunci. Niebuhr maintains that Ausones is the Greek form of the native name Auruni, from which the adjective form Aurunicus, shortened into Auruncus, would come. This interchange of *s* and *r*, in certain positions, is not at all uncommon. Suessa Aurunca, near the Liris, was in the centre of the country which the Ausones occupied. Cales (Livy, viii. 16), Ausona, Minturnæ, and Vescia (ix. 25) were Ausonian cities. Livy (viii. 15, 16) seems to speak of the Aurunci of Suessa and the Ausones of Cales as two different people; the former were the enemies, the latter the allies of the Sidicini. The explanation must be, that the Ausones of Cales, and the Aurunci of Suessa, were both Ausones or Aurunci (it is indifferent which term we use), and that one part of the nation, at the period referred to, was hostile to the Romans, and the other part friendly to them. (See Niebuhr, i. 63, &c., English translation; and OSCI.) Lower Italy, and sometimes even all Italy, is designated by the term Ausonia. Cowper uses it in this sense—

"Nor for Ausonia's groves
Of golden fruitage and her myrtle bowers."

AUSPICES (*Auspicia*). For a brief view of the Roman superstition upon which the ceremony of the auspices was founded, the reader is referred to AUGUR. It is there stated that the greater part of the Roman magistrates, before they entered upon their office, went through the ceremony of inauguration, which was supposed to confer upon them the protection of heaven. When the Roman empire had greatly extended itself, it was no longer possible for the small body of augurs on all occasions to perform their duties in person; and it was therefore conducive to the public service that the magistrates themselves who had been inaugurated should be supposed to have received from that ceremony some share in the divine privilege. Thus they too were able to deduce the pleasure of heaven from the movements of birds and the other signs which belonged to the sacred science. Originally, this power was peculiar to the patrician members, and the privilege was employed as an argument for excluding the plebeians from the higher magistracies; but eventually, when the plebeians had acquired a right of admission to the consulate, prætorship, &c., they also necessarily had the privilege of the auspices attached to these magistracies. Still, to the very last, those offices which in their origin were purely of a plebeian character, as the tribunate, had no connection whatever with the auspices. There were many niceties in the law of auspices, which were matters of dispute among the Romans themselves, and were referred from time to time to the college of augurs, or sometimes to a single member of that body. The most important distinction was that which existed between the greater and the less auspices: thus the auspices of a consul were superior to those of a prætor; and consequently the latter, it was ruled, could not preside at a consular election.

In an army the commander-in-chief received the auspices with the *imperium*, and so completely was any success attributed to this privilege, that if any part of his army under any inferior officer, in any part of the world, gained a victory, that success was attributed to the commander-in-chief, who perhaps might have been the whole time in the neighbourhood of Rome, and he alone was entitled to the honours of the triumph. In this case the lieutenant was said to fight under the auspices of the commander-in-chief. As the ceremony of the auspices was originally employed to sanction the commencement of every important undertaking, whether public or private, the word *auspicari*, 'to take the auspices,' came at last to bear the signification of commencing any matter of importance.

AUTHENTIC, in music, a term used in the ancient ecclesiastical modes [MODES], but unknown in modern music. When the octave is divided harmonically, as in the proportion 6, 4, 3,—that is to say, when the fifth is below and the fourth above, for example,

then the mode is called *authentic*. When the octave is divided arithmetically, in the proportion 4, 3, 2,—that is, when the fifth is above the fourth, for example,

the mode is then called *plagal*.

Dr. Pepusch says, "When the fugue is in the fifth above or below, or in the fourth above or below, then one of the parts is in the *authentic*, the other in the *plagal* mode of the key we compose in." Handel's chorus, 'He trusted in God,' in the 'Messiah,' may be adduced as an example of this, where the subject is in the authentic mode, the answer in the plagal.

AUTHENTICA, a barbarous Latin version of the Novellæ of Justinian [JUSTINIAN'S LEGISLATION], so called by early writers on the civil law, from its being a literal translation from the original Greek. (Ducange, 'Gloss. ad verbum.')

AUTO-DE-FE' (Act of Faith), or, as it is termed by the Spaniards, with whom it was most in use, AUTO-DA-FE', was the public and solemn reading of extracts from the trials promoted by the Inquisition, and of the sentences pronounced by the judges of that tribunal. At this form or act the offenders themselves were present, or in case of their death or unavoidable absence, their bones or effigies were substituted for them; there were also present the civil authorities and corporate bodies of the town where it was performed, particularly the criminal judge, into whose hands the offenders were delivered, that he might inflict upon them the punishment prescribed by the laws; the fire, gallows, and executioners having been previously prepared by order of the inquisitors. When this execution was performed with the highest pomp and ceremony, it was called *auto público general*, general and public act. There was also an *auto particular*, private act, at which the inquisitors and criminal judge only were present; the *autillo*, held in the halls of the Inquisition, in the presence of such persons as the inquisitors invited, and of the ministers of the tribunals alone; and, finally, the *auto singular*, held in the church, or in the public square, against a single individual. The punishment was inflicted for what had been decided to be heresy by the Inquisition. On May 21, 1559, 31 persons were thus executed at Valladolid, and 37 were remitted to prison for a subsequent auto-da-fé, which took place on Sept. 24, at Seville, when 24 persons were burnt, and 80 subjected to other punishments, nearly all on charges of Lutheranism.

In the different autos-de-fé which have been celebrated in Spain, from the first which took place at Seville in 1481, to the abolition of the tribunal by Napoleon Bonaparte in 1808, no less than 34,658 persons were executed, either publicly or secretly; 228,214 victims suffered various other punishments; and 18,049 were executed in effigy. The last auto, according to Llorente, was the *auto singular*, celebrated in December, 1815, at Mexico, against a certain ecclesiastic named Morellos, accused of heresy. He was absolved from the charge of heresy, but was afterwards hung by order of the viceroy for high treason, as being concerned in a plot to effect the emancipation of Mexico from Spain.

The suppression of the Inquisition was confirmed by the Cortes in 1813, but it was reinstated by Ferdinand VII. in 1814; there were, however, no public executions under it, though many imprisonments, and in 1820 the Inquisition was again formally abolished by the legislature.

AU'TOGRAPH, from the Greek αὐτόγραφον, *written with one's own hand*, an original manuscript; the handwriting of any person.

This word, in relation to manuscripts, is used in opposition to an apograph, or copy.

Collections of autographs, as the handwritings of individual persons, had their origin about the middle of the 16th century in Germany, where the gentry, and especially persons who travelled, carried about with them white-paper books, to obtain and preserve in them the signatures of persons of eminence, or new acquaintance; when such a book received most generally the name of Album; though it was sometimes called 'Hortus,' or 'Thesaurus Amicorum.' Persons who travelled, it is to be observed, showed, by such means, what sort of company they had kept. (See the facts mentioned in Izaak Walton's 'Life of Sir Henry Wotton,' Reliq. Wotton. edit. 1651; and Wanley's 'Account of the Harleian Manuscript 933, in his Catalogue.') These albums are frequently found in the manuscript libraries of Europe. Several are preserved in the British Museum, and some are adorned with splendid illuminations, one, which is now exhibited to the public, is the 'Album Amicorum' of Christopher Arnold of Nuremberg, containing a collection of German and English autographs, among which is one of John Milton, with a sentence in Greek, dated London, November 19, 1651. The oldest (MS. Sloan. 851) bears a date as early as 1578, and appears to have belonged to a lady: others will be found in the MSS., Sloan. 2035, 2360, 2597, 3415, 3416. There is one also in the same repository, preserved in the library which belonged to George III., evidently made for Charles I., with whose and his queen's mottoes and signatures it opens. "1626. Si vis omnia subjicere, subjice te rationi, Carolus, R." "En Dieu est mon espérance, Henriette Marie, R." The other signatures with short sentences, English and foreign, are numerous, all upon paper, but with alternate leaves of vellum, bearing rich illuminations of the arms of the respective parties inserted. Amongst them are the signature and arms of Charlotte de Trémouille, countess of Derby, afterwards the celebrated defendress of Latham House.

The earliest royal autograph of England, now known, is the small figure of a cross, made by the hand of king William Rufus, in the centre of a charter, by which the manor of Lambeth was granted to the church of Rochester. This charter is preserved amongst those which were bequeathed some years ago to the British Museum by Lord Frederick Campbell. The next royal autograph known is *Le Roy R. E.*, the signature of Richard II., affixed to two documents, one preserved in the archives of the Tower of London, the other relating to the surrender of Brest, among the Cottonian manuscripts. From his time the royal signatures of England continue in uninterrupted succession.

We sometimes read of the signing of Magna Charta, which really means the sealing; a signature at that period was not the authentic attestation of an instrument, or even of a letter.

Autographs possess some interest, but not in themselves as historical documents; such an interest is independent of the autograph; but the handwriting of an eminent person, as the production of his mental and bodily powers, is the most peculiarly his own, and therefore, perhaps, the most interesting relic of his former life. Lavater, and others since his time, have believed that the character of an individual was shown by his writing. It may be true to some extent; and there is a general character in the writing of different nations and of different periods. The vivacity and variableness of the Frenchman, and the delicacy and suppleness of the Italian, are perceptibly distinct from the slowness and strength of pen discoverable in the writing of the German, Dane, and Swede; and it may be that when we are in grief we do not write as we do in joy. But numerous causes must always counteract or obstruct that analogy which many think the handwriting of an individual bears to his character; and none more than that close imitation which the hand of an assiduous scholar is likely to bear to that of his instructor. The form and fashion of Roger Ascham's handwriting is clearly perceptible in the autographs of Edward VI. and Queen Elizabeth.

In later times, collections of autographs have been formed far more extensive than those which the Germans made in the 16th and 17th centuries. There is a very numerous assemblage of them in the British Museum, where many of the most interesting are exhibited under glass to the general public in the large saloon known as the King's Library; among them are not only letters and signatures, but MS. volumes, such as the Iliad and Odyssey of Pope, written chiefly on the backs of letters, and the original draft of Dr. Johnson's 'Irene.' There are also many extensive private collections of autographs in England. The interest attached to autographs and the desire to possess them, has much increased in modern times. The autograph of Shakspere, now in the British Museum cost 100*l.*, and that in the Library of the City of London, 158*l.* In general the value set upon an autograph, and the price it brings when sold by auction, depends on the eminence of the individual and the scarcity of specimens of his handwriting. To furnish individuals desirous of possessing such, but the rarity of which precluded the chance of obtaining them, the 'Autograph Miscellany' was begun in 1855, and continued for some time. The work consisted of a collection of autograph signatures, letters, and documents, lithographed in folio, by F. Netherclift.

The first English work in which a series of fac-similes of autographs appeared, was Sir John Fenn's 'Original Letters from the Archives of the Paston Family,' published in 1787; followed by 'British Autography,' a collection of fac-similes of the handwriting of royal and illustrious personages, with their authentic portraits, by John Thane, 3 vols. 4to, 1789—1791. Another work, more extensive and more correct, will be found in 'Autographs of Royal, Noble, Learned, and Remarkable Personages, conspicuous in English History, from the Reign of Richard II., to that of Charles II.,' by John Gough Nichols, fol. Lond. 1829; from the preface to which some of the preceding particulars have been derived. See also Fontaine's 'Manuel de l'Amateur d'Autographes,' Paris, 1836; the Essay on 'Die Autographensammlungen,' in the 'Deutschen Vierteljahrsschrift' for 1842; and Paignot, 'Recherches sur les Autographes.'

AUTO'MATON, derived from two Greek words, meaning *self-moved*, is a name generally applied to all machines which are so constructed as to imitate any actions of men or animals. We may pass over the pigeon of Archytas, the clock of Charlemagne, the automaton made by Albertus Magnus to open his door when any one knocked, the speaking head of Roger Bacon, the fly of Regiomontanus, and several others, not knowing whether their performances may not have been exaggerated. They serve to show, however, that the idea of applying machinery to imitate life is of very ancient date, and that considerable success was not deemed impossible.

In the 'Memoirs of the Academy of Sciences' for 1729, a description is given of a set of actors representing a pantomime in five acts. But previously to this, M. Camus had described an automaton group which he had constructed for the amusement of Louis XIV., consisting of a coach and horses, &c. The coachman smacked his whip, and the horses immediately set off, moving their legs after the manner of real horses. The carriage turned at the edge of the table on which it was placed, and when opposite to the king it stopped, a page got down and opened the door, on which a lady alighted, presented a petition with a curtsey, and re-entered the carriage. The page then shut the door, the carriage proceeded, and the servant, running after it, jumped up behind it. (Hutton, 'Mathematical Recreations,' vol. ii. p. 95.) This is nearly inconceivable, and requires strong corroborative testimony.

The flute-player of Vaucanson is fully described in the 'Enc. Meth.,' article 'Androide.' It was exhibited at Paris, in 1738, where it was seen by M. D'Alembert, who wrote the above article. It really played on the flute, that is, projected the air with its lips against the embouchure, producing the different octaves by expanding and contracting their opening; forcing more or less air, in the manner of living performers, and regulating the tones by its fingers. It commanded three octaves, the fullest scale of the instrument, containing several notes of great difficulty to most performers. It articulated the notes with the lips. Its height was nearly six feet, with a pedestal, in which some of the machinery was contained.

Two automaton flute-players were exhibited in this country some years ago, as perfect as the preceding, except in the articulation. They were of the size of life, and performed ten or twelve duets. That they really played the flute, any bystander could prove, by placing the finger on any hole which for the moment was unstopped by the automaton.

The automaton trumpeter of Maelzel, the inventor of the metronome, exhibited at Vienna, is thus described in the 'Journal des Modes' for 1809. From a tent M. Maelzel led out a martial figure, in the uniform of a trumpeter of the Austrian dragoon regiment Albert, his trumpet being at his mouth. After having pressed the figure on the left shoulder, it played not only the Austrian cavalry march, and all the signals of that army, but also a march and an allegro by Weigl, which was accompanied by the whole orchestra. After this, the dress of the figure was completely changed into that of a French trumpeter of the guard; it then began to play the French cavalry march, all the signals, and lastly, a march of Dussek, and an allegro of Pleyel, accompanied again by the full orchestra. The sound of this trumpet is pure, and more agreeable than that which the ablest musician could produce from that instrument, because the breath of the man gives the inside of the trumpet a moisture which is prejudicial to the purity of the tone. Maelzel publicly wound up his instrument only twice, and this was on the left hip."

In 1741, M. Vaucanson produced a flageolet-player who beat a tambourine with one hand. The flageolet had only three holes, and some notes were made by half-stopping these. The force of wind required to produce the lowest note was one ounce; the highest, fifty-six pounds (French). Its construction was altogether different from that of the flute-player.

The same year, M. Vaucanson produced a duck, which has been considered as the most ingenious of his performances. It dabbled in the water, swam, drank, and quacked like a real duck; and the peculiar motions of the animal were very successfully imitated. It raised and moved its wings, and dressed its feathers with its bill. It extended its neck, took barley from the hand and swallowed it; during which the natural motion of the muscles of the neck was perfectly perceptible. It digested the food it had swallowed by means of materials provided for its solution in the stomach. The inventor made no secret of the machinery, which excited great admiration at the time.

Several other automata are described by Hutton; in particular one constructed by M. Droz, which drew several likenesses of public characters. A machine which wrote and drew, and another which performed on the pianoforte, were also exhibited some years ago in London.

The celebrated chess-player, once regarded as an automaton, is now a solved mystery. A boy was concealed inside the figure. The great difficulty existed only so long as it was imagined that the player was outside the figure; nevertheless, the machinery by which the hands were regulated must have been ingenious.

The passion for making automata has not yet quite passed away. A recent example was Mr. Faber's *Euphonia*. It consisted of a draped bust and waxen-faced figure, which articulated language with a certain degree of intelligibility. The sounds were produced by pressing on sixteen keys. A small pair of bellows was worked with the nozzle in the back part of the head of the figure; and in the head were various arrangements of India-rubber and other materials, calculated to yield a particular sound in each part or section. When the exhibitor wished to produce a sentence or word, he first mentally divided it into as many parts as there are actually distinct sounds—not necessarily coinciding with the syllables or the single letters; since the various phonographic systems far more correctly represent distinct sounds. Having determined the first word, the operator pressed his finger on a particular key, which admitted a blast of air to a particular compartment, in which the mechanism was of the kind to produce the sound required. Other keys were similarly pressed, until all the required sounds of the word or sentence were produced. The sounds were sufficiently analogous to those of the human voice to convey the meaning intended, but they had an unpleasant effect on the ear. By a modification of the action, whispering was imitated.

A remarkable machine was the *Automaton Latin Versifier*, introduced in 1845, by Mr. John Clark, of Bridgewater, after a labour of thirteen years. At the first thought such an invention seems inexplicable, owing to the mental character of the process; but a little inquiry shows that it is only a system of permutations, such as a machine can easily be made to produce. The specimens given in the 'Athenæum' and other public journals at the time are all Latin hexameters, and moreover have all the same grammatical formula and scansion, in respect to dactyls and spondees. The following nine specimens were given, each complete in itself as an hexametric line, but having no connection with the others:

1. Horrida sponsa reis promittunt tempora densa.
2. Sontia tela bonis causabunt agmina crebra.
3. Bellica vota modis promulgant crimina fusca.
4. Aspera pila patet depromunt prælia quædam.
5. Effera sponsa fere confirmant vincula nequam.
6. Barbara tela reis præmonstrant nubila dura.
7. Horrida vota bonis progignunt jurgia crebra.
8. Sontia castra modis prositant somnia fusca.
9. Trucida regna quidem conquirunt opera cara.

The exterior of the machine which composed these lines resembled in size and shape a small bureau bookcase; in the frontispiece of which, through an aperture, the verses appeared in succession as they were composed. Mr. Clark, in a communication to the 'Athenæum' (No. 923) made the following observations on his machine:—"The machine is neither more nor less than a practical illustration of the law of evolution. . . . . The machine contains letters in alphabetical arrangement; out of these, through the medium of numbers, rendered tangible by being expressed by indentures on wheel-work, the instrument selects such as are requisite to form the verse conceived: the components of words suited to form hexameters being alone previously calculated, the harmonious combination of which will be found to be practically interminable."

Mr. A. J. Cooley, in the same journal, pointed out the existence of a forgotten pamphlet, a century and a-half old, in which the author showed how, from a table given, a person might produce millions of hexameter lines. But these were produced by accumulations of words; whereas Mr. Clark's machine, if we rightly understand his description, actually builds up the lines letter by letter.

In 1856 a strange automatic group was exhibited in London. A figure representing a monkey held a violin, moved a bow across the strings, pressed the fingers alternately on them, and clapped its jaws together in token of satisfaction. A hare browsed, or seemed to browse, at a cabbage. A goat uttered an audible cry. A doll-child, that had been quietly reposing in its cradle, woke up uneasily, and screamed aloud for its "Pa" and "Ma." The doll was a failure, in regard of resemblance to a living child; but the monkey, hare, and goat were cleverly constructed, the internal machinery being covered with the real skin of the animals; the form of each animal being well imitated by padding within the skin; and the slight movements of each animal, such as the twinkle of the eye and the twitch of the tail, being reproduced with great exactness.

It affords matter for regret that so much ingenuity should be expended on the production of automata leading to no useful results. There are, however, many machines—for calculating, numbering, registering, stamping, pageing, &c.—which illustrate the application of automatic action to useful purposes. Some of these will be noticed under CALCULATING MACHINES.

AUTOPHON, a kind of barrel-organ, the tunes of which are produced by means of perforated sheets of mill-board, instead of pins or studs, as in the ordinary barrel-organs.

AUXILIARY VERBS are distinguished from other verbs in the following way. Verbs express the notions of *action:* auxiliary verbs, though they originally expressed notions of action, only express *relations of action* when considered as auxiliary verbs, and are accordingly employed, in connection with other verbs, to give to them certain relations called by grammarians tense, mood, and voice. The modern languages of Europe, and our own more particularly, abound in such forms; but they are likewise found in the languages of Greece and Rome, sometimes altogether undisguised, more commonly so completely blended with the main verb as to pass for a mere arbitrary suffix, which the grammarian does not attempt to explain. It is in the very nature of a particle which plays a secondary part, that it should not occupy too large a share of the attention; and thus those verbs which in course of time are used as auxiliaries, though originally as significant as any other verbs, lose something of their distinctive character; so that if the fuller form happen to disappear from a language, the corrupted auxiliary presents anomalies which it is not easy for the philologist to explain. This difficulty is increased by the circumstance, that verbs used as auxiliaries generally throw off much of the distinctive meaning which they originally possessed.

Among the auxiliaries, the most important is the substantive verb signifying *to be;* and, as might be expected, no word has passed through more variations of form. Grimm and other grammarians, indeed, have laid down, that there are three, or even more, distinct roots combined in the conjugation of this verb. But when allowance is made for the known changes that take place in the letters of the alphabet, there will appear, we think, some reason for supposing that all the varying forms of this verb are derived from a common origin.

As the ultimate form from which all the rest appear to us to have flowed, we will propose the root *wes;* and we are inclined to assign to this root, as its primary meaning, the notion of *eating.* Such a form appears in the Latin *vescor* (pronounced wescor), *I eat*, and in the German *wes-en, to be.* The initial *w*, it is well known, sometimes assumes the form of *g*, and hence we have *ge-gess-en, eaten.* Again, as the German verb *lesen* to read forms a past tense, *er las* he read, so *wesen* accounts for the form *was*, common, as the past tense, to English and German. Still more commonly the *w* is altogether dropped, and then we have the root *es*, which is the basis of the Greek substantive verb *es-mi* (the original form), *es-si, es-ti* (still existing in this form in the Lithuanian language), of the old Latin verb *es-um, es, es-t, es-umus, es-tis, es-unt, es-to, es-se*, and with a slight variation of the Sanskrit *as-mi*, &c. With the same form of the Latin we may connect *es-t, he eats, es-se, to eat, es-ca, es-culentus*, &c., and the German *ess-en, to eat.* After the word has thus been stripped of its initial consonant, the short vowel also was apt to disappear, at least in the longer forms. Thus from the old Latin forms *esum, esunt, esim*, &c., there arose the shorter forms *sum, sunt, sim*, &c.; *prae-es-ens, ab-es-sens*, were reduced to *praesens, absens;* and in German we find *sein, to be, sind, they are*, in place of *es-ein, es-ind.*

In the second place, the consonant *s* interchanges with the letter *r*, so that *were* exists by the side of *was*, and *art, are*, with *is.* Thus in the Latin too we have *er-am, er-o.* where more regular forms would have been *es-am, es-o.* Again, the same letter *s* is interchangeable with the dentals *t, d.* Hence, while the Germans have *ess-en, ich ass*, the English express the same notions by *to eat, I ate;* and the Latin tongue uses indifferently *ed-it* or *es-t, he eats, ed-ere* or *es-se, to eat.*

The form *be* is evidently the parent of the German *bin, I am, bist, thou art*, and of the English *be-ing* and *be-en.* With the short vowel changed, it appears in the Lithuanian *bu*, as *bu-ti, to be, buwau, I have been;* and as *b* in English generally corresponds to *f* in Latin, we must claim the Latin *fu-vi* or *fu-i, fu-am, fu-turus*, &c. That these forms are all related among themselves is generally allowed; but the question now proposed is, whether they are not also radically connected with the root *wes.* If it could be shown that the root *be* ever existed with an *s* at the end, it would no longer be thought a violent step to suppose a connection between *bes* and *wes*, more especially when we find the *b* already half way towards a *w* in *fui.* Now, a strong presumption that the root *be* had a sibilant, arises from the old German form *bir-umes, we are*, compared with *war-umes, we were*, in the same language (see Grimm's 'Deutsche Grammatik'). In these words the suffix, which denotes the plural pronoun, cannot claim more than four letters *umes*, thus agreeing very precisely with the Doric Greek suffix *omes*, the Latin *umus*, and the Lithuanian *ame* of the same power. The radical parts then are *bir* and *war;* and as we know the latter to be connected with the form *was*, there is no slight suspicion that *bir* implies an early form, *bis.* If the Greeks lost the *s* in many of their forms derived from the short root *es*, as they did, and if we ourselves have dropped it from *am*, we can scarcely be surprised at its disappearance from the longer form *bes* or *bis.* The notion that the roots *bes* and *wes* are connected, is confirmed again by the other forms in these languages, which represent the idea of eating. In Greek, we find *bo-sco, bo-tos, bo-ra*, in Latin *pasco, pascor*, as well as *vescor.*

The use of this auxiliary in the passive, both in ancient and modern languages, is familiar to all; but it has been less carefully observed, that it is likewise employed in the perfect tenses of the active voice, at least in the Latin language. *Amav-eram, amav-ero, amav-issem, amav-isse*, evidently contain the forms *eram, ero, essem, esse;* and in the perfect subjunctive, an older form, *amaresim*, may be inferred from the three existing forms *amassim, amaverim, amarim;* and in *amavesim* we see the full form *esim* which preceded *sim*. We have left out *amavi* from the series, solely because it would require some space to demonstrate what is yet undoubted, that here too the verb *es*, be, entered. Indeed, in the form *amavistis* we have all we need desire. Probably we ought to have divided the Latin forms just quoted so as to give the *v* to the suffix, *ama-veram*, in which case the Latin perhaps exhibits what is virtually the *w* of *wesen* and *was*.

After the verb *to be*, the next in importance among the auxiliaries is the verb *habe-re*, Latin, *to have;* in German, *hab-en*. Like the preceding verb, this also has undergone great corruptions. In the English *hast, has, had*, the main consonant has already disappeared. While in the Italian *ho*, from the Latin *habeo*, we find nothing of the root but the aspirate, and even that is often omitted, so that we should doubt the connection between the words, but for the first and second persons plural. But as we shall have further occasion for the forms of this verb in the Roman languages of Europe, we will place here the present tenses :—

Latin,	habeo,	habes,	habet;	habemus,	habetis,	habent.
Italian,	ho,	hai,	ha;	abbiamo,	avete,	hanno.
Spanish,	he,	has,	ha;	habémos or hémos,	habéis,	han.
French,	ai,	as,	a;	avons,	avez,	ont.

The use of the verb *to have* in the formation of the perfects, so universal in the modern languages derived from Latin, may be occasionally seen in the parent language also, where such phrases as *furem constrictum habeo, fures constrictos habeo*, differ but slightly in meaning from *furem constrinxi*, &c.; and there was the greater necessity for adopting a new formation, as the Latin perfect unites two tenses in itself, namely, the aorist and the present-perfect. It will be seen too from the examples which we have given, why, in the derived tongues, the participle in some cases agrees with the accusative; as *je les ai tués*. But the use of *habeo* as an auxiliary is not confined to the perfect tenses. In connection with the infinitive it forms a convenient periphrasis for a future. From the Italian infinitive *sentir*, we have a future *sentir-o, -ai, -a, -emo, -ete, -anno*, the first and second persons plural, now they are used as suffixes, being reduced as completely as the rest. In the Spanish verb *hablár* the future is *hablar-é, -as, -á, -émos, -éis, -án;* and in the French from *sentir* there is formed *sentir-ai, -as, -a, -ons, -ez, -ont*. In the tense called generally the conditional, the infinitive is again employed. The Italians unite with it their perfect tense of *to have*, derived from *habui*, namely, *ebbi, avesti, ebbe, avemmo, aveste, ebbero;* and their conditional is *sentir-ei, -esti, -ebbe, -emmo, -este, -ebbero*. On the other hand, the French employ *avois*, which may be proved to have been derived from the Latin imperfect *habebam;* but as *avons, avez*, of the present dropped their radical letters *av*, when attached as suffixes to the future, so also *avois*, &c., throughout lose the same letters in forming the conditional, thus, *sentir-ois, -ois, -oit, -ions, -iez, -oient*. The Spanish language, in like manner, employs the imperfect *había, habías, había, habíamos, habíais, habían*, derived also from *habebam*, &c.; and thus, with the same suppression of the first two letters, the conditional of *hablar* is *hablar-ía, -ías, -ía, -íamos, -íais, -ían*. This view of the formation of the futures is of service in explaining the apparent irregularities so often found in those tenses, which moreover generally extend to the infinitive. This explanation of the futures and conditionals in these three languages we take from the writings of the French philologist Raynouard.

Many other verbs of the Latin language have become auxiliaries in the derived languages: 1. *Vado*, Lat. *I go*, is employed thus by the Italians, as *io vo faciendo, I am doing;* and in French for a future, *je vais parler, I am going to speak*. 2. *Venio*, Lat. *I come*, in Italian as an equivalent for the verb *to be, egli vien riputato, he is considered;* in French to denote an action just passed, *il vient de trouver, he has just found*. 3. *Ambula-re*, Lat. *to walk* (corrupted into the Italian *andare* and the French *aller*), is used in the former language thus, *andra rovinato, he will be ruined;* and in the French, *il alloit dîner, he was going to dine*. 4. *Sta-re*, Lat. *to stand*, in Italian *sono stato, I have been, sta scrivendo, he is writing;* and the French *étois* or *étais* (formerly *estois*) is a corruption from *stabam*, precisely as *aimois* from *amabam*. The Spaniards, besides several of the auxiliaries here mentioned, use *tener*, derived from the Latin *tene-re, to hold*, but not exactly as an auxiliary verb: and besides *ser, to be*, they have *estár, to be*, from the Latin *stare*. In the Teutonic languages the auxiliary verbs are very numerous, and our own language contains nearly the whole of them: 1. *may, might*, are the present and perfect of the same defective verb. In the German we find an infinitive of this verb *mög-en*, as well as the forms *mag*, and *mochte;* 2. *can* and *could* correspond to the German *kann* and *konnte* from the infinitive *könn-en;* 3. *will* and *would* to the German *will* and *wollte* from *woll-en;* 4. *shall* and *should* to *soll* and *sollte* from *sollen*, originally meaning to owe.

But though the German auxiliaries correspond with the English as to their having a common origin, they have a use which is not quite the same. "In general, *possibility* is expressed by *können, dürfen* (the English *dare, durst*), *mögen*, and *necessity* by *müssen* (the English *must*), *sollen, wollen; lassen* (the English *let*) implies necessity as well as possibility." (Becker's 'German Grammar,' p. 65.) The German word *haben*, like the corresponding English *have*, and the German *werden*, when used alone, are notional verbs, or verbs expressing a distinct notion and not a mere relation: thus we can say, *er wird reich, he becomes rich;* but in the expressions *ich werde kommen, I will come, die frage wird von ihm beantwortet, the question is answered by him*, the verb *werden* is used as an auxiliary for the future tense and the passive voice respectively.

AVALANCHES are the most dangerous and terrible phenomena to which the valleys embosomed between high, snow-topped mountain ranges are exposed. They are especially frequent in the Alps, owing to the steepness of their declivities, but they are also known in other mountain regions, as in the Pyrenees, in Norway, and in the Himalaya. They originate in the higher region of the mountains, when the accumulation of snow becomes so great that the inclined plane on which the mass rests cannot any longer support it. It is then pushed down the declivity by its own weight, and precipitated into the subjacent valley, where it often destroys forests and villages, buries men and cattle, and sometimes fills up the rivers and stops their course. Besides these destructive effects, it has been stated that persons are often killed and houses overthrown by the sudden compression of the air, caused by the incredible velocity with which these enormous masses finally descend. But this subject does not appear to have been philosophically examined; the statement must be regarded as doubtful.

Four different kinds of avalanches may be distinguished: drift avalanches, rolling avalanches, sliding avalanches, and glacier or ice avalanches, of which the first commonly take place in the early part of winter, the second and third at the end of winter and in spring, and the last only in summer.

The drift or loose snow avalanches (called, in Switzerland, staublauinen) take place when heavy snow has fallen in the upper region of the mountains during a still calm, and this accumulated mass, before it acquires consistency, is put in motion by a strong wind. The snow is driven from one acclivity to another, and so enormously increased in its progress, that it brings down an incredible volume of loose snow, which often covers great part of a valley. The damage caused by these avalanches, is, however, generally not very great, because most of the objects covered by them may be freed from the snow without having sustained great damage; but they are said often to produce such a compression of the air that houses are overturned, and men and cattle suffocated. This latter effect, if rightly attributable to such a cause, has not yet been explained.

The rolling avalanches are much more dangerous and destructive. These take place when, after a thaw, the snow becomes clammy, and the single grains or flocks stick to one another, so as to unite—by the process of regelation, first recognized by Faraday and since investigated by Tyndall [ICE,]—into large hard pieces which commonly take the form of balls. Such a ball, moved by its own weight, begins to descend the inclined plane, and all the snow it meets in its course downwards sticks firmly to it. This snow-mass, increasing rapidly in its progress, and descending with great velocity, covers, destroys, or carries away everything that opposes its course—trees, forests, houses, and rocks. This is the most destructive of avalanches, and causes great loss of life and property. In the year 1749, the whole village of Rueras, in the valley of Tawich, in the canton of the Grisons, was covered, and at the same time removed from its site, by an avalanche of this description; but this change, which happened in the night time, was effected without the least noise, so that the inhabitants were not aware of it, and on awaking in the morning could not conceive why it did not grow day. A hundred persons were dug out of the snow, sixty of whom were still alive, the interstices between the snow containing sufficient air to support life. In the spring of 1755, after a very low barometer, and enormous falls of rain in the plains and snow in the mountains of Piedmont, many destructive avalanches took place, by which two hundred persons were killed. One of them, on the 19th of March, overwhelmed the village of Bergemoletto, in a manner fatal to many of the inhabitants; but two women and a girl, who had taken shelter from the rigour of the weather in a stable, after remaining under the mass of snow for thirty-seven days, were dug out alive, and eventually recovered from the effects of their confinement and privations. The avalanches of the Savoy Alps, and the circumstances of this event, are described in a somewhat celebrated Italian work by Ignazio Somis, Professor of Medicine in the University of Turin, and physician to Charles Emanuel III. king of Sardinia, published at Turin in 1758, and of which an English translation appeared in 1765. He enters into a physiological and experimental investigation of the case, and of the condition of the sufferers, both during and after their misfortune, ascribing their preservation to the continual disengagement of fresh air from the melting snow; and as it has been proved that the air in melted snow and in rain water contains much more oxygen than that of the atmosphere, it is probable that this assisted to counteract the effects of want of ventilation, and that therefore Somis was right in his conclusion, though the state of pneumatic chemistry at the time precluded his knowing all the facts of the case. In 1806, an avalanche descended into Val Calanca, likewise in the canton of the Grisons, transplanted a forest from one side of the valley to the other, and placed a fir tree on the roof of a parsonage-house. In 1820, sixty-four persons were killed in Fettan, in the high valley of Engadin, in the country of the Grisons; and, in the same year, eighty-four persons and four hundred head of cattle, in Obergestelen, and twenty-three persons at Brieg, both situated in the canton of Valais. In the same country, the village of Briel was almost entirely covered by an avalanche in 1827.

Many thousands of strong trees are destroyed by these avalanches, either by being broken off near the ground, or by being rooted up, shivered to pieces, and thus precipitated into the valley. Where the avalanches are of common occurrence, the inhabitants of the valleys know the places where they come down, and by observing the changes of the weather, they are able to foretell the time of their descent. They also endeavour to protect themselves by preserving the forests in the paths of the avalanches, and by erecting massive edifices of a particular construction, placed against projecting rocks.

The sliding avalanches (rutsch lauinen, also called suoggi (pron. suggy) lauinen in Switzerland) originate on the lower and less steep declivities, when, after a long thaw in spring, those layers of the snowy covering which are nearest the ground are dissolved into water, and thus the bond is loosened which unites the mass to its base. The whole snowy covering of a declivity then begins to move slowly down the slippery slope, and to carry before it everything which is too weak to withstand its pressure. When an object does not directly give way to the mass, it is either borne down by the snow accumulating behind it, or the whole mass divides, and proceeds in its course on each side of it.

The ice or glacier avalanches are nothing but pieces of ice which formerly constituted a part of a glacier, but, loosened by the summer heat, are detached from the principal mass, and precipitated down with a noise like thunder. They are commonly broken into small pieces by the rocks which they meet in their progress. When seen from a distance, they resemble the cataracts of a powerful stream. In the valley of Grindelwald, in the canton of Berne, they may be often seen; and at the base of the Jungfrau, the noise which accompanies their fall is almost continually heard. They are less destructive than the other avalanches, because they descend only upon places which are not inhabited.

Occasionally the avalanches change their character in their progress. When the declivity is not too great, and the ground under it not too slippery, the mass of snow begins to slide; but arriving at a precipitous descent, its velocity and its mass are greatly increased, and it begins to roll. If, at this stage of its course, it meets a strong, craggy rock, the mass is instantly divided into innumerable small pieces, and thus it appears at the end of its progress like a drift avalanche.

In the spring season, travellers in the Alps take every precaution to avoid being overwhelmed by these falls of masses of snow. The guides urge them to refrain from causing noise, lest the agitation of the air should occasion an avalanche. In Switzerland, for the same reason, the mule-bells are made silent, and in dangerous localities, before descending into the valleys, it is usual, by the discharge of fire-arms, to determine the fall of the snow which a concussion of the atmosphere may bring down.

Avalanches is the common French expression for these natural phenomena; but in those districts of France which are situated between the ranges of the Alps, they have other names: as avalanges, lavanches, lavanges, lavanzes, lids, lits, lydts. The drift avalanches are also termed lauvines venteuses, and the rolling, lauvines joncières. In Italian they are called lavina, lavine, labine, and valanca; and in the Rhetic dialect of the Grisons, lavina and lavigna. Among the German inhabitants of Switzerland, they are named lauinen, lauwinen, lauwen, leuen, lowen, and lahnen. In the Pyrenees they are sometimes called congeres; and in Norway, snee-shred, and snee-fond. (Kasthofer's 'Observations on a Journey through the Alps,' &c.)

The avalanches or snow-slips of northern India have been noticed by Dr. Thomas Thomson, F.R.S., in his 'Western Himalaya and Thibet.' In Rondu, on the Indus, in February 1848, the progress of the thaw, he states, occasioned constant avalanches, the snow slipping from the steep sides of the ravines, and when once in motion, advancing with constantly increasing momentum, till it reached the lowest level. "All day long," he relates, "the mountains echoed with the sound of falling snow; the avalanches were not often visible, as they took place in the ravines, but now and then (where the ravines terminated in precipices) they were seen pouring in cataracts of snow over the face of the cliffs. In each large ravine which joined the Indus I found one of these gigantic avalanches, and was enabled to see that they were composed of a congeries of balls of snow, varying in diameter from one to six feet, and often containing fragments of rock in their centre. Many of these snow-streams were not less than forty or fifty feet thick. At the level of the Indus they were now very soft, and evidently thawing rapidly."

At Kharbu, in the Dras valley, early in April, the fallen avalanches, universal in the ravines, were cut off abruptly by the river (a tributary of the Indus), forming cliffs of snow fifteen or twenty feet high, in which the structure and development of the mass by successive slips, alternating with falls of snow, could be distinctly made out. One or two of them still crossed the river, which flowed below the bridge of ice thus formed. In the northernmost valley of Cashmere, that of the river Sind, another affluent of the Indus, in one of the ravines which furrow the mountain slopes, Dr. Thomson witnessed the descent of one of these avalanches, having been warned by the sound that it was approaching, and had time to attain a place of safety before it came near. When it came into sight, the ravine, which was narrow and deep, was completely filled by balls of snow of various dimensions, which continued to flow past for several minutes. The snow-slip terminated in the river, which was speedily blocked up for two-thirds of its width with an immense accumulation of snow. The narrow rocky gorge of the river, further to the south, after the 16th of April, was in many places still blocked up with snow, which had descended in avalanches down the ravines, and had accumulated in the bed of the stream; the travellers having three times to cross the river on these snow beds.

In the Himalaya, therefore, as in Europe, the agency of the process of regelation is evident; the partially melted snow, from the time of its beginning to slip, gradually resuming its frozen condition, as it accumulates into balls, and finally into masses.

AVANTURINE GLASS. [GLASS MANUFACTURE.]

AVATA'RA is a Sanskrit word, which properly signifies "a descent, or the act of descending"—for example, from a boat or other vehicle,—but is particularly applied to the incarnations of the Hindoo deities, or their appearance in some manifest shape upon earth. Our information regarding the successive development of religious and mythological ideas among the Hindoos, is not yet perfect. It appears, however, that the doctrine of the Avatâras belongs to a comparatively recent period, and are chronicled with considerable variations in different Puranas. Those portions of the Vedas or sacred writings of the Hindoos to which, from the style and structure of their language, the highest antiquity may with safety be attributed, inculcate the worship of elements and deified natural powers, but do not allude to those apparently more spiritualised deities that require to be invested with a bodily frame to operate in the material world.

The number of the Avatâras mentioned in the Puranas, or legendary poems of the Hindoos, is very great. Those of Vishnu alone, who is distinguished by the character of 'Preserver' in the Trimûrti, or triad of the principal Hindoo deities, are stated to be endless. They are variously enumerated; but all accounts seem to agree in selecting the following ten as the most conspicuous:—

1. *Matsya*, the Fish, under which form Vishnu preserved Manu, the ancestor of the present human race, during a universal deluge.

2. *Kûrma*, the Tortoise, which incarnation Vishnu underwent in order to support the entire earth, when the celestial gods and their opponents the Asuras, or Daityas, were churning the sea (using Mount Mandara as a churnstaff) for the beverage of immortality (amrita).

3. *Varâha*, the Boar. Vishnu, with the head of a monstrous boar, is represented as slaying Hiranyâksha, the chief of the Asuras, who had taken possession of the celestial regions, and as uplifting the earth, which had been sunk to the bottom of the sea.

4. In his incarnation as *Narasinha*, a being half man and half lion, Vishnu killed Hiranyakasipu, the brother of Hiranyâksha.

5. The form of *Vâmana*, the Dwarf, was assumed by Vishnu to humble the pride of King Bali. He went to a sacrifice which the king was performing, and supplicated for as much ground as he could measure with three steps, which request being granted, the dwarf suddenly grew to an immense size, and with his steps comprised earth, mid-air, and heaven.

6. Vishnu appeared in a human form, as *Parasurâma*, the son of Jamadagni and Rênukâ, in order to preserve mankind, and especially the Brahmans, from the tyranny of the military tribe of the Kshatriyas.

7. Vishnu was born as the four sons of King Dasaratha, and, under the names of *Râma*, *Lakshmana*, *Bharata*, and *Satrughna*, in order to destroy Râvana, the Daitya sovereign of Ceylon, and other demons who were then infesting the earth. The actions of Râma, who was the chief hero, form the subject of a celebrated epic poem in Sanskrit, called the Râmâyana, and attributed to the ancient sage Vâlmiki. One of the most remarkable of his exploits is, that he is said to have "humbled the pride of Parasurâma," who, as just mentioned, was an incarnation of Vishnu also; and the cause of the humbling is stated to have been the slaughter of the Kshatriyas.

8. The most celebrated of the Avatâras of Vishnu is his appearance in the human form of *Krishna*, in which he is supposed to have been wholly and completely incarnate, whereas the other Avatâras are only considered as emanations from his being. Krishna assisted the family of the Pândavas in their war with the Kurus, and through them relieved the earth from the Daityas and the wicked men who oppressed it. The history of this conflict is told at length in the Mahâbhârata, another great epic poem in Sanskrit. He also slew Kansa, the king of Mathura, after a number of adventures.

9. *Buddha* is, by the followers of the Brahmanical religion, considered as a delusive incarnation of Vishnu, assumed by him in order to induce the Asuras to abandon the sacred ordinances of the Vedas, by which they lost their strength and supremacy.

10. *Kalki* is the name of an Avatâra in which Vishnu will appear at the end of the Kaliyuga, or present age of the world, to destroy all vice and wickedness, and to restore the world to virtue and purity.

We cannot enumerate the Avatâras of the inferior deities, in which the mythology of the Hindoos abounds. There is no mention of any Avatâr of Brahmâ and of Siva, the two supreme deities who, with Vishnu, constitute the Trimûrti; they are only repeated births, always in the form of a youth, but of various colours. In the seventh volume of the 'Asiatic Researches' (Calcutta, 1801) may be seen an account given by Captain Edward Moor of an incarnation of Ganesa, or Ganapati, which had, since the year 1640, become hereditary in the family of Mooraba Gosain, a Brahman, at Punah. Mrs. Graham, who in 1809 visited this living Avatâra, which was then a child, has given an interesting notice of it in her journal.

(See the articles MANU, RAMA, KRISHNA, and BUDDHA; Bohlen, *Das alte Indien*; Vans Kennedy, *Researches into the Nature and Affinity of Ancient and Hindu Mythology*, 4to, London, 1831; H. H. Wilson, *The Vishnu Purana; a system of Hindoo Theology and Tradition*, 4to, 1840.)

A'VE MARI'A, the two first words of a short Latin prayer or invocation to the Virgin Mary, said by Roman Catholics in their orisons. As a prayer it only became established in the 13th century when it was enlarged, and in 1508 it was completed and finally sanctioned by Pope Pius V. The first part of the prayer is merely a repetition of the salutation of the angel to Mary on her conception. (St. Luke, i. 28.) The second part is an entreaty to the Virgin "to pray for the salvation of sinners now and at the time of their death." The recital of the Ave Maria generally follows that of the Pater Noster, or Lord's Prayer.

Ave Maria is also in Italy the name of a particular time of the day, about half an hour after sunset, when the church bells ring, and pious persons leave off for a moment their occupations or pastimes and ejaculate the Ave Maria. It is also called the Angelus in other catholic countries. To this custom Byron alludes in these fine lines,—

> Ave Maria! blessed be the hour!
> The time, the clime, the spot where I so oft
> Have felt that moment in its fullest power
> Sink o'er the earth so beautiful and soft,
> While swung the deep bell in the distant tower,
> Or the faint dying day hymn stole aloft,
> And not a breath crept through the rosy air,
> And yet the forest leaves seem'd stirr'd with prayer.
>
> *Don Juan*, Canto III.

In many churches, and especially convents, the bells are also rung at the first dawn of day, and this is called in Italy the morning Ave Maria, *l'Ave Maria del giorno.*

AVERAGE is a quantity intermediate to a number of other quantities, so that the sum total of its excesses above those which are less, is equal to the sum total of its defects from those which are greater. Or, the average is the quantity which will remain in each of a number of lots, if we take from one and add to another till all have the same; it being supposed that there is no fund to increase any one lot, except what comes from the reduction of others. Thus, 7 is the average of 2, 3, 4, 6, 13, and 14; for the sum of the excesses of 7 above 2, 3, 4, and 6—that is, the sum of 5, 4, 3, and 1—is 13; and the sum of the defects of 7 from 13 and 14—that is, the sum of 6 and 7—is also 13. Similarly, the average of 6 and 7 is $6\frac{1}{2}$. To find the average of any number of quantities, *add them all together, and divide by the number of quantities.* Thus, in the preceding question, add together 2, 3, 4, 6, 13, and 14, which gives 42; divide by the number of them, or 6, which gives 7, the average.

It must be remembered that the average of a set of averages is not the average of the whole, unless there are equal numbers of quantities in each set averaged. This will be seen by taking the average of the whole, without having recourse to the partial averages. For instance, if 10 men have on the average 100*l.*, and 50 other men have on the average 300*l.*, the average sum possessed by each individual is not the average of 100*l.* and 300*l.*; for the 10 men have among them 1000*l.*, and the 50 men have among them 15,000*l.*, being 16,000*l.* in all. This, divided into 60 parts, gives 266*l.* 13*s.* 4*d.* to each. A neglect of this remark might lead to erroneous estimates; as, for instance, if a harvest were called good because an average bushel of its corn was better than that of another, without taking into account the number of bushels of the two.

The average quantity is a valuable common sense test of the goodness or badness of any particular lot, but only when there is a perfect similarity of circumstances in the things compared. For instance, no one would think of calling a tree well grown because it gave more timber than the average of all trees; but if any particular tree, say an oak, yielded more timber than the average of all oaks of the same age, it would be called good, because if every oak gave the same, the quantity of oak timber would be greater than it is. It must also be remembered that the value of the average, in the information which it gives, diminishes as the quantities averaged vary more from each other; but this and other points connected with averages will be mentioned more fully in the article MEAN, this being the mathematical word which is used in the same sense as average in common life.

AVERAGE. In Marine Insurance this term is applied to the mode and ratio of compensation for losses, not being total losses of both ship and cargo. Average is of two kinds, 'General' and 'Particular.'

General Average is a term used indiscriminately, sometimes to denote the *kind of loss which gives a claim to general average contribution*, and sometimes to denote *such contribution itself.* To avoid confusion it is better to use the term *general average loss* when speaking of the *former*, and *general average contribution* when speaking of the *latter.* All losses which give a claim to general average contribution may be divided into great classes:—1. Those which arise from extraordinary *sacrifices* of part of the ship or part of the cargo, purposely and reasonably made in order to save the whole adventure from perishing. 2. Those which arise out of extraordinary *expenses* incurred for the joint benefit of both ship and cargo. Losses of the first class, and those limited to jetsam of cargo, are alone mentioned in the text of that Rhodian law which is generally regarded as the foundation of the whole doctrine of general average; *jactus factus levandæ vadis patiâ.* A general average loss may be defined to be, "a loss arising out of extraordinary sacrifices made, or extraordinary expenses incurred, for the joint benefit of ship and cargo." A general average contribution may be defined to be "a contribution by all parties in a sea adventure, to make good the loss which has been sustained by one or more of their co-adventurers, from sacrifices made or expenses incurred for the general benefit." This contribution is assessed upon each adventurer in proportion to the value of his *whole* property actually at risk as, or as though, finally saved by the *sacrifice*, or at the time it was benefited by the *expenditure.* This contribution is ordinarily insured against; and when ascertained by *adjustment of general average*, is settled by the underwriters.

Particular Average loss differs from general average loss, both as to its cause and the mode of its compensation. It is a partial loss arising from damage accidentally and proximately caused by the perils insured against, or from extraordinary expenditure necessarily incurred for the sole benefit of some particular interest, as of the ship alone, or the cargo alone. This damage or expenditure, instead of being contributed for by the general body of adventurers, falls entirely upon the *particular* owner of the property deteriorated by the damage, or benefited by the expenditure; and such owner, if insured, has a claim against his underwriter in proportion:—1st., to the degree by which the damage sustained, or the expenditure to be refunded, may have diminished the value to him of the property as insured; and 2nd, to the sum insured.

It may further be observed, that certain charges called *Petty Averages*, being the ordinary charges at the places of loading and unloading, and during the voyage, and formerly borne *one-third* by the ship, and *two-thirds* by the cargo, are now usually compounded for in bills of lading by provision for the payment of 5 per cent. calculated on freight, and 5 per cent. more for primage charged on the captain—'primage and average accustomed.' A good deal of difficulty and complication often arises upon the adjustment of averages, and 'Averages Staters' now carry on a distinct business in commercial countries. (Arnould on 'Marine Insurance and Average,' 2nd edit., p. 894, et seq.)

AVOCA'T, a French word, derived from the Latin *advocatus*, and corresponding to the English counsellor at law. [ADVOCATE.] In French law language the avocats are distinguished into avocats plaidans, who answer to our barristers, and avocats consultans, called also jurisconsultes, a kind of chamber counsel, who do not plead in court, but give their opinion on intricate points of law. Under the old monarchy the avocats were classed, with regard to professional rank, into various categories, such as avocats au conseil, who conducted and pleaded causes brought before the king's council; they were seventy in number, and were appointed by the chancellor; they were considered as attached to the king's court: and avocats généraux, who pleaded before the parliaments and other superior courts, in all causes in which the king, the church, communities, and minors were interested. At first the avocats généraux were styled avocats du roi, and the other barristers who pleaded in private causes were called avocats généraux, but towards the end of the 17th, or the beginning of the 18th century, these appellations were changed, the avocats du roi were styled avocats généraux, and three of them were appointed to each superior court, while the counsel who filled the same office before the inferior courts assumed the name of avocats du roi. ('Répertoire Universel de Jurisprudence,' and 'Dictionnaire de l'Académie.') Avocat fiscal was a law-officer in a ducal or other seignorial court of justice, answering to the avocat du roi in a royal court.

At present there are in France avocats au conseil d'état; avocats généraux, of whom there are five at the Court of Cassation or Supreme Court, four at the Cour Impériale of Paris, besides substitutes, and two or three at each Cour Impériale in the departments. The practising barristers are classed into avocats à la Cour de Cassation, who are fifty in number, and who conduct exclusively all causes before that court; and avocats à la Cour Impériale, who plead before the various imperial courts. All avocats must be licentiates in Law, take the oath before a court of appeal (Cour Impériale), and show that they have a domicile in Paris. There is a roll of the advocates practising in each court. Candidates are admitted by the Council of Discipline after a probationary term. The members of the council are elected by ballot, by the advocates inscribed on the roll, and their functions last for the judicial year. The avoués (attorneys), are public ministerial officers, whose business it is to represent the parties before the court and before the tribunals, although their duty, strictly speaking, is to place the judges in a position to come to a decision (postuler), and to present to them in the form of abridged propositions the claims of the parties (conclure) yet they may in some cases undertake the defence orally, as, for example, when the number of advocates is not sufficient for the despatch of business (R. Jones's 'History of the French Bar'). The word avoué, in canon law, meant the protector or guardian of some church, abbey, or monastery, or other ecclesiastical community and jurisdiction, and by their authority all contracts relating to these corporations were made; in some ancient charters we find proofs that in gifts to the church or monastery, the conveyance was made personally to the avoué. In the middle ages he was generally some feudal lord who took care of the temporal interests of the community, and defended them either in court or field. Thus Charlemagne accepted the title of avoué of St. Peter; Hugh, that of St. Riquier; and mention is made by Bolland, of letters of Pope Nicholas, constituting St. Edward, king of England, and his successors, avoués of the monastery of Westminster and of all churches in England. The avoué dispensed justice in the name of the ecclesiastical superiors in all places under their jurisdiction, and commanded the forces assembled in their defence. In German he was called "kastvogt;" the name occurs often in the history of the middle ages.

AVOIDANCE OF A BENEFICE. [BENEFICE; CESSION.]

AVOIRDUPOIS, or AVERDUPOIS, the name given to the common system of weights in England, now applied to all goods except the precious metals and medicines. Thus, a pound of tea is a pound *averdupois*, and contains 7000 grains; a pound of gold is a pound *troy*, and contains 5760 grains. The word has been supposed to be derived from the French *avoir du poids*, to have weight; but considering that *averdupois* is the more ancient mode of spelling the word, and that the obsolete French verb *averer*, and the middle Latin word *averare*, signify to *verify* (see Ducange, at the word *Averare*), it is more likely that we are to look here for the true etymology. It has also been supposed that the word is derived from *averia ponderis*, *averia*, and *avera*, being (on the same authority) words used for goods in general.

The ounce averdupois is generally considered as the Roman *uncia*. It contains $437\frac{1}{2}$ grains (N.B. there is but one grain in use amongst us), while the Roman *uncia*, according to Arbuthnot, contains $437\frac{1}{2}$ grains; according to Christiani ('Delle Misure,' &c., Venice, 1760, cited by Dr. Young), it is $415\frac{1}{10}$ grains; and according to Paucton (cited by Dr. Kelly), it is $431\frac{1}{2}$ grains. Whether the preceding be correct or not, we cannot suppose that in any case the supposition could be nearly verified, as our ancestors do not appear to have been very attentive to small weights: for instance, in the list of church gold and silver plate delivered to Henry VIII. (preserved in the Bodleian library), nothing less than an ounce is mentioned, except only once, in which a quarter of an ounce is given.

The ancient pound (now used in Scotland) was heavier than the averdupois, and weighed 7600 grains: the earliest regulations on the subject fix the *troy* weight; the averdupois is mentioned in some orders of Henry VIII., in 1532, and a pound of this sort was placed in the Exchequer as a standard by Elizabeth in 1588. The committee of 1758 found this pound to be $1\frac{1}{2}$ grain less than it should be as deduced from the standard troy pound kept at the Mint, which they attributed to frequent use; but considering the averdupois weight altogether as "of doubtful authority," and troy weight as the one "best known to our law," they recommended the adoption of the latter as a standard, which it has accordingly been ever since, though goods in general are weighed by averdupois weight.

The committee of 1816 made no alteration in the weights, but ascertained the value of the grain, as afterwards described in the Act of Parliament 5 Geo. IV. c. 74: "A cubic inch of distilled water, weighed in air by brass weights, at the temperature of sixty-two degrees of Fahrenheit's thermometer, the barometer being at thirty inches, is equal to two hundred and fifty-two grains, and four hundred and fifty-eight thousandth parts of a grain." The pound averdupois contains 7000 such grains. From this it may be deduced that a cubic foot of water, under the above conditions, weighs 997·14 ounces, which, being very nearly 1000 ounces, gives an expeditious rule for roughly deducing the real weight of a cubic foot of any substance from its specific gravity. For example, if the specific gravity of gold be 19·36, the weight of a cubic foot of gold is 19,360 ounces averdupois. If more accuracy be required, subtract three for every thousand from the result.

The averdupois pound is divided as follows:—

Grains.	Dram.		
$27\frac{11}{32}$	1	Ounce.	
$437\frac{1}{2}$	16	1	Pound.
7000	256	16	1

28 pounds make one quarter.
112 pounds, or 4 quarters, one hundred weight.
20 hundred weight, one ton.

The ounce is more commonly divided into quarters than into drams
The usual contractions are as follows:—

grain	gr.	pound	lb.
dram	dr.	quarter	qr.
ounce	oz.	hundred weight	cwt.

To reduce a large number of pounds to hundred weights roughly, *from all but two figures take all but three.* Thus 17,684 pounds contain 159 hundred weight, done as follows:—

	176
Subtract	17
	159

The pound averdupois is ·45354 of the French kilogramme, and ·9071 of the common French pound. That is, 904 pounds are 410 kilogrammes, and 452 pounds averdupois are 410 French pounds [WEIGHTS and MEASURES].

If decimals be employed: from one *hundredth* of the pounds subtract one *thousandth*, and from the result subtract its *hundredth* part. The result is about one five-hundredth part too small. We give the preceding example, and another which is an obvious verification:—

17,684 llb.	112 llb.
176·84	1·12
17·68	·112
159·16	1·008
1·59	·010
157·57	·998

AVOWRY. [REPLEVIN.]

AVOYER is a term derived from the Latin *advocatus*. *Avoué* or *Avoyer* was no doubt a French form or corruption of *advocatus*, and was applied in general to the lay champion or guardian of the church. In South Germany and Switzerland, however, a country so anciently and universally of ecclesiastical organisation, the officers who ruled as deputies of the emperor were induced to designate their authority by the title which was most general in the country, viz., the title implying ecclesiastical authority. Thus we find in the beginning of the 13th century, Berthold, Duke of Zähringen, styled the emperor's *advocatus* in these regions, and Rodolph afterwards was advocatus of Suevia. This term, half Germanised, half Gallicised (for the Burgundians then governed the plains of Western Switzerland), became in common parlance *Avoyer*, and was assumed by the magistrates of such towns as had attained the rank of *Imperial*. This meant that they belonged nominally to the emperor, which privilege rendered them independent of, and on a level with, the feudal aristocracy. The magistrates of Swiss cities assumed the title of *Avoyer*, to which the German term Schultheissen is equivalent, but the title sunk everywhere into disuse, except at Berne, in which town it lasted till the revolution of 1794.

In an amusing account of Switzerland (published in 1704), by Temple Stanyan, Esq., the reader will find a full description of the dignity and duties of these officers, who were two in number and were at the head of the government of the Canton, retaining their employments for life, but exercising them annually by turns.

AWARD. [ARBITRATION.]

AXIOM, a word derived from the Greek ἀξίωμα, which is formed from the Greek verb ἀξιόω, *to think worthy of*; and thence to *desire* or *demand*. It was not used in the time of Euclid, by whom the principles which we call axioms are termed *κοιναὶ ἔννοιαι*, or *common notions*. The word was not in universal use as late as the year 1600, at which date we find "*communis sententia*" preferred to "*axioma*." (See Chambers' edition of 'Barlaam,' Paris, 1599.)

The term axiom was originally peculiar to geometry, in which science it came to mean a proposition which it is necessary to take for granted. It is usual to define an axiom as a *self-evident proposition*; but this, though a true description of all the axioms which are found necessary, is not a good definition. In the first place, it is well known that the geometer must deduce the properties of space in the best way he can, from the smallest possible number of the most evident principles; and it must be his study so to choose them, that his own mind, or that of his pupil or opponent, shall be at the least possible expense of concession. But he cannot say beforehand that his science *shall* be deduced from self-evident principles. Imagine a person of cultivated reasoning powers first approaching geometry, and capable of being made to take a view of the general objects of the science. It would not appear to him certain that he should be able to deduce all the properties of figure from those which are self-evident; on the contrary, he might suspect that he would be obliged to have recourse to actual measurement, in order to verify some essential preliminaries. At least no answer could be given to him, if he did express such a suspicion, except a reference to the science itself; and this clogs an axiom, defined as a self-evident proposition, with a condition which can only be verified by subsequent study.

In the second place, a self-evident proposition, as such, ought not to be called an axiom, because it is not admitted as such in geometry, however evident it may be, provided it can be proved from those propositions which *are* called axioms. That two sides of a triangle are greater than the third, has a greater degree of evidence than some of the admitted axioms; yet it is not taken for granted, because it can be deduced from these.

The Epicureans are said to have laughed at geometry, because, among other things, it proves the proposition that two sides of a triangle are greater than the third; which, said they, is evident even to a jackass, who always makes practical use of it in going from one place to another. This evidently arises from the mistake that a geometrical axiom is self-evident, and that all self-evident propositions ought to be axioms. And the oldest remaining opponent of geometry, Sextus Empiricus, has a chapter upon the subject ('Pyrrhoniarum Hypotyposeon,' lib. ii. cap. 11); on which, as on most other things of the same sort, it may be safely averred that the axioms of geometry themselves are much clearer than the axioms of psychology on which the opposition to them is grounded. For it is not to be supposed that the opponents of axioms take first principles which are more evident than that "the whole is greater than its part," or that "two straight lines cannot inclose a space."

The necessity that there should be some axioms is evident from the process of reasoning. The deduction of propositions from the comparison of other propositions must have a beginning somewhere, so that there must be at least two propositions to begin with, the evidence of which is derived from other sources than reasoning. Every attempt which has been made to dispense with axioms altogether, has, as might be expected, proved unsuccessful; somewhere or other in the process assumed theorems have been found.

The more modern discussions which have arisen about axioms appear to us to proceed from some fallacy of this sort, that the idea conveyed by the whole of a sentence must be more complicated than that conveyed by any one of its parts; or at least, that it must always be necessary to enter separately upon the consideration of the auxiliary forms of speech in which a simple idea is conveyed, before that idea can be said to be explained. As an instance, in that most simple of all propositions, "two and two are the same as four," which by itself is comprehended as soon as spoken, we have the (by itself) difficult phrase "are the same," implying identity, and leading, if pursued far enough, to many very abstruse metaphysical considerations. These, in their proper science, and considered with reference to other objects, are not misplaced; but, as applied to geometry, are not only unnecessary, but subversive of the natural order of reasoning; for however much may be said upon maxims, axioms, first principles, or by whatever name they may be called, there remains the simple proposition, "two and two are the same as four," clearer, as a whole, than any one of the explanations, illustrations, or comments, which have been brought to its aid. There is however this to be said for many writers who have endeavoured to make such points better known than they are already; namely, that the older writers, in their love of what is called the *à priori* method, had filled their books with notions against which it was necessary to contend; whence sprung a confirmed habit of reasoning upon the nature of self-evident propositions. Locke (book iv. chap. 7), 'On Maxims,' can hardly be intelligible to a reader who has not some knowledge of what the school writers have said upon our simplest perceptions, which rendered it necessary to contend both against words without meaning, as when they said some such thing as that "knowledge is the likeness of the thing known, formed in the knowing faculty;" and also against assumptions of a very dubious character, such as "general propositions are known, at least sometimes, before particular ones."

All the oldest manuscripts of Euclid, the summary of Boethius, the commentary of Proclus, the Arabic translations, and the earlier European editions, agree in what is no doubt Euclid's plan, of distinguishing assumptions distinctly relating to space, under the name of *postulates* (αἰτήματα), from assumptions which equally relate to other kinds of magnitude, under the name of *common notions* (κοιναὶ ἔννοιαι). We cannot find out who first made the alteration which Robert Simson has adopted: it appears in Gregory's Greek text. This modern alteration converts the postulate into an assumed *problem*, and the axiom into an assumed *theorem*; but the distinction of propositions into problems and theorems does not exist in Euclid's work; it is an addition of editors. The more recent Greek texts have returned to Euclid's distinction, and we hope translations will in time follow them. We give Euclid's collection of postulates and common notions at length.

Postulates.—1. Let it be granted, from any point to any point, to draw a straight line. 2. Also, to lengthen a finished straight line, and continue it straight. 3. Also, with any centre and radius (διάστημα, meaning *interval measured from that centre*) to describe a circle. 4. Also, all right angles are equal to one another. 5. Also, if a straight line, falling upon two straight lines, make the angles which are within and upon the same side less than two right angles, the two straight lines, being lengthened without end, shall meet one another upon that side on which the angles are less than two right angles. 6. Also, two straight lines cannot inclose a space.

Common Notions.—1. Things equal to the same are equal to one another. 2. Also, if equals be added to equals, the wholes are equals. 3. Also, if from equals equals be taken, the remainders are equals. 4. Also, if to unequals equals be added, the wholes are unequals. 5. Also, if from unequals equals be taken, the remainders are unequals. 6. Also, things which are double of the same are equal to one another. 7. Also, things which are halves of the same are equal to one another. 8. Also, things which fit one another (have the same boundary) are equals. Also, the whole is greater than the part.

Euclid has not stated *all* the properties of space which he takes for granted. It is our belief that his work was not written for elementary students, but was a controversial treatise on the question, Can geometry be formed into a demonstrated system, resting upon definite postulates? We imagine that when he collected his postulates, six in number, and put them forward at the head of the first book, he did not thereby intend to collect everything which he assumed, but only his own selection from the theorems the postulation of which had been matter of discussion. The theorems which all parties had admitted without question among postulates, we suspect him to have left unnoticed. In the following list will be found Euclid's postulates, with the substitutions we have recommended above, and all the postulates which are tacitly assumed; giving, we believe, a full account of all the theorems relating to space and figure only, which the student of the first six books will be required to assume:—

1. Any two points may be joined by a straight line. 2. Any terminated straight line may be indefinitely lengthened. 3. A circle may be drawn with any centre, and any distance terminated at that centre as a radius. 4. Any point is within or without a circle, according as its distance from the centre is less or greater than the radius. 5. A line drawn from a point within a figure to a point without, cuts the boundary of the figure. 6. A straight line which passes through a point within a figure, will, if sufficiently produced, cut the boundary of the figure in two points, one on each side of the point. 7. A figure may be removed without any alteration of figure from one part of the plane to another, and may be turned round before removal. 8. If two straight lines coincide in two points, they coincide altogether, both between the points and beyond them. 9. A straight line being indefinitely produced both ways, any line drawn from a point on one side of it to a point on the other, must cut the straight line. 10. Two lines which cut one another cannot both be parallel to any third line. 11. If a smaller area be cut out from a larger, the area left is the same from whatever part of the larger the smaller may be taken.

It would hardly be possible to make a list of *all* the "common notions" which Euclid employs. The postulates, or notions concerning space and figure, are the things on which it is most important to dwell with precision.

What is required to be conceded in the first three postulates, is not that a straight line or circle can be imagined to be drawn, in the sense usually attached to these words, but that the *geometrical* line can be drawn, which is *length without breadth.* This is impossible, mechanically speaking, the line being a conception of the mind which cannot be executed. [LINE.]

The last of the "postulates" is a self-evident property of the straight line, a term incapable of other definition than that which is contained in its properties; that is, we can make no use of the obvious notion conveyed in the words "straight line," unless we admit some one or other of its distinguishing characteristics, which is more definite than saying that it lies evenly between its extreme points. We might appear to avoid an axiom by saying, let the name "straight" line be given to that species, no two of which can, under any circumstances, inclose a space; but in that case we should need another axiom—namely, we should require it to be granted that there is such a thing as the straight line so defined, and that we have not assumed any contradiction in supposing the above species of lines to exist. It must be remembered, that though the definitions are placed at the beginning in Euclid, it is not thereby implied that the terms defined are really possible. "Let lines which, being in the same plane, do not meet, though ever so far produced, be called parallels," does not mean us to assume that such lines do exist, but only, that when they shall have been proved to exist, the name by which it is agreed to call them has been given. But some of the definitions, which ought therefore to be distinguished from the rest, are tacitly accompanied by the assumption of existence of the things defined.

The 4th postulate is a theorem of more difficulty than the subject requires; since, with one additional assumption respecting the straight line, it admits of proof. The assumption previously discussed, namely, that two straight lines cannot enclose a space, amounts to assuming that if two straight lines coincide in two points, or if two different points of the one can be made to lie upon two different points of the other, the portions of the straight lines *lying between these points* will also coincide entirely. Let it be granted, in addition, that the parts which are *not* between these points will coincide (an equally evident proposition), and the 4th postulate of Euclid admits of proof. Euclid's editors, in taking this postulate for granted, make use of it to prove our additional assumption, which, as they phrase it, is "no two lines can have a common segment;" that is, two lines cannot coincide between two points and not coincide elsewhere. But, of two propositions, one of which it is found necessary to assume, that one should be the more simple of the two.

The 5th postulate, which is a theorem of some difficulty, neither self-evident, nor even easily made evident, is not at all required in the form given, even in Euclid. For he proves, without its assistance, that if the two lines there mentioned meet, it must be on the side on which the angles are less than two right angles. But it may be reduced to a very evident form as follows: If a straight line be taken, and a point exterior to it, of all the straight lines which can be drawn through the point, one *only* will be parallel to the first-mentioned straight line. The whole assumption lies in the word *only;* for Euclid shows, without the help of this axiom, that a parallel can be drawn, and how to draw it.

This axiom is the cause of the celebrated discussion on the theory of PARALLELS, under which head it will be more fully treated.

AXIS, AXE. This word is used in so many different senses, that it may be defined as follows: Any line whatsoever which it is convenient to distinguish by a specific term with respect to any motion or other phenomenon, is called the axis. Thus we have axes of co-ordinates, of oscillation, of inertia, of rotation, of polarisation, &c., under which heads definitions will be given.

The word, when used by itself, generally means either axis of *Rotation*, or axis of *Symmetry*. An axis of rotation, or revolution, is the line about which a body turns; an axis of symmetry is a line on both sides of which the parts of the body are disposed in the same manner, so that to whatever distance it extends in one direction from the axis, it extends as far in the direction exactly opposite. Or if perpendiculars to the axis be drawn from all points and in all directions through the body, the whole of each perpendicular which is within the limits of the body will be bisected by the axis. Such is the middle line of a cone, any diameter of a sphere, the line drawn through the middle of the opposite faces of a cube, &c.

AXLE. Since the extensive use of locomotives, the theory of the action of axles, and the causes of their fracture, have been subjects of elaborate inquiry among engineers. Whether solid or hollow axles, with a given weight of metal, are the stronger, is one among these inquiries. Mr. Yorke, in a paper read before the Institute of Civil Engineers in 1843, contends for the superior strength of hollow axles; but this conclusion is disputed by others. The theory of axles may, indeed, be considered at present in a tentative state; meanwhile, patents are frequently obtained for improvements in form and in mechanical action. Hardy's patent axles have shown the possession of such a remarkable degree of toughness, that the Privy Council in 1849 granted a continuation of the patent; and remarks were made in the House of Lords relating to the lessening of railway accidents by their use. Since that period the patent has been sold for a considerable sum to a company at Birmingham, established for the manufacture of these axles on a large scale.

Rowan's patent axles are intended to lessen the amount of friction usually produced by the action of a wheel on its axle. For the axle in common use is substituted a small centre revolving arm, along which are fitted five or six rollers, closed at each end; the sheath over the rollers revolves with very little friction, as it touches upon a small portion only of each of the rollers. The arm is turned truly parallel, with a bevelled shoulder to fit a corresponding bevel on the rollers; and a screw-nut is fitted in the extremity of the arm, having also a bevelled shoulder. The rollers are fitted into and carried by two rings in such a manner that they are perfectly free to move on their centres; and, when placed on the arm, are free also to move round it without lateral motion, being confined by the bevels. By this contrivance the bearing is transferred to the surfaces of the rollers, and does not affect their centres.

Mr. Bessemer, in a 'Treatise on Railway Axles,' considers the probable causes why the axles of railway carriages break more frequently than those of a road vehicle, in spite of the fact that the one go upon smooth rails, while the other pass over roughly paved surfaces. He attributes it to the oscillation of a railway carriage. The flanges of the two wheels are alternately driven up close against the rails by this oscillation, and whenever this occurs, there is a momentary tendency in one wheel to revolve a little faster than the other; and thus a strain or twist is given to the axle, first in one direction and then in the other. This straining may take place five thousand times in an hour in a railway carriage in rapid motion; and Mr. Bessemer conjectures, that the iron of the axle may in this way be thrown into a molecular state liable to fracture. To obviate this source of mischief, he proposes the use of a compound axle, formed of two pieces so united endwise that, while the ordinary action of an axle is maintained, the two halves may yield a little during oscillation, instead of being subjected to a twist in the fibre of the metal.

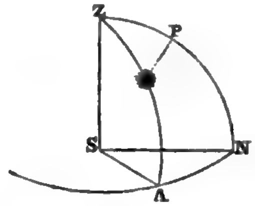
AYEEN AKBERY, properly *Ayîn-i-Akbari*, is the title of a geographical and statistical account of the Mogul empire in India during the reign of the emperor Jelâleddin-Mohammed-Akbar, written by his vizir Abu'l Fazl. [ABUL FAZL and AKBAR, in BIOG. DIV.] It constitutes the third or concluding part of the 'Akbarnameh' of the same author. The first volume consists of a summary account of Akbar's ancestors, and the second volume comprises the occurrences of his reign, from his accession to the throne down to the 47th year. A free and often abridged translation of this work into English was undertaken by Mr. Francis Gladwin, and a portion was issued in Calcutta as early as 1783. It has more than once been reprinted in England. As an original and we may say an official account of the internal organisation of the Mogul empire at the time of its greatest prosperity, the 'Ayîn-i-Akbari' is highly interesting. It is divided into four parts: the first three are chiefly political and legislative; the fourth part is chiefly statistical and geographical, giving a description of the several provinces at that time comprehended under the Mogul government, and a detailed account of the ancient institutions, religion, and literature of the Hindoos, which is very comprehensive, and in many parts surprisingly accurate.

AYUNTAMIENTO, JUSTICIA, CONCEJO, CABILDO, REGIMIENTO, are the names given in Spain to the councils of the towns and villages. These councils are in general composed of the corregidor, alcalde, regidores, jurados, and personeros, or hombres-buenos. All these officers, with the exception of the corregidor, who was always appointed by the government, were originally elected every year by the inhabitants of the concejo or commune. To be the head of a family, a native of Spain, and settled in the commune, were the only qualifications required either from an elector or a candidate. The origin of this institution may be traced to the remotest period of Spanish history. (Masdeu's 'Historia Critica,' vols. iv. to ix., more particularly vol. viii. book 3.) It has been ever the most cherished and the most carefully preserved of all their privileges by the Spanish people. It was chiefly by the ayuntamientos that the resistance to the French under Buonaparte was rendered so persevering and so obstinate; and it was the law against them in 1840, which created so much dissatisfaction in the country as enabled Espartero to succeed in exiling the regent-queen Christina. (For a full account of them, see Mariana, 'Examen de la Antigua Legislacion de España;' 'Recopilacion de las Leyes de estos Reinos,' book vii.; Mariana, 'Historia de España,' book xx. chap. 13.)

AZADIRINE. An alkaloid of uncertain composition, found in the *Melia Azadirachta*.

A'ZIMUTH, a corrupted Arabic word, which when properly written is *as-samt*, the *as* being the article *al*, assimilated to the initial letter of the word to which it is prefixed; *samt* means 'a way, a road, a path;' also 'a part, tract, country, or quarter.'

Azimuth denotes the angular distance of the horizontal point which is directly under a star from the north point of the horizon. Thus if



S be the spectator, Z his zenith, Z N his meridian, N A the horizon, and Z A the vertical circle passing through a star *, then the angle A S N is the star's azimuth, or it is the angle made by the vertical circle Z A and the meridian Z N.

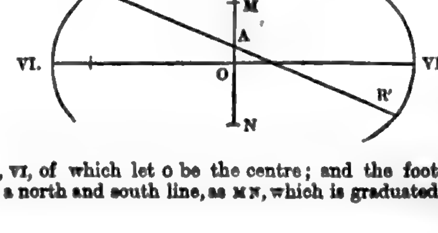
The only instruments in use by which the azimuth could be immediately observed are the theodolite and the altitude and azimuth circle. [THEODOLITE; CIRCLE.] It is not one of those elements which are usually measured in astronomy. When the star is known (that is, when its declination is known), the azimuth can be found by observing the altitude A * and solving a spherical triangle; for in the triangle whose sides are the complements of the star's altitude, the star's declination, and the latitude of the place, the azimuth is the angle opposite to the complement of the declination, as may be seen in the triangle Z P *, where P is the pole. Similarly the latitude of the place may be found when the altitude and azimuth of a known star are observed at the same moment. For in the triangle just mentioned, Z * and * P are given, and the angle * Z P; whence Z P may be calculated. When the azimuth of a star is found by means of an instrument adjusted by the magnetic needle, then the azimuth obtained (which needs a correction on account of the deviation of the needle) is termed the *magnetic azimuth*. In this way the deviation of the needle may be found at any known place by observing the magnetic azimuth and calculating the true azimuth by observing the altitude of a star in the manner before described.

An instrument is said to be moved in *azimuth* when it is turned on a vertical axis, so that any line in it drawn through the axis points to the same altitude in the heavens, but not to the same azimuth. Similarly an instrument is moved in *altitude* when it is turned on a horizontal axis. An altitude and azimuth instrument is one which admits of both motions.

It is hardly necessary to observe that when the star is in the horizon, and when the azimuth is less than 90°, (90°—azimuth) is the amplitude (which see); and that when the azimuth is greater than 90°, (azimuth —90°) is the amplitude.

An *azimuth circle* is a circle all the points of which have the same azimuth, that is, a vertical circle. For azimuth Compass, see COMPASS.

AZIMUTH or ANALEMMATIC DIAL is one whose plane is parallel to the horizon, and whose gnomon, or stile, is moveable in a vertical position. The hour-points are in the periphery of an ellipse,



as VI, XII, VI, of which let O be the centre; and the foot of the stile moves in a north and south line, as M N, which is graduated from O to M and from O to N in tangents of the sun's declination, from zero to $23\frac{1}{2}$ degrees, the radius of the circle being equal to the eccentricity of the ellipse. To these graduations are annexed as many corresponding days of the month as can be introduced.

In order to investigate the place of any hour-point, as R, let A be the foot of the stile for any given day. Then AR will be the direction of the shadow for the given hour; and there must be found the azimuthal angle MAR, or its supplement MAR′. Now the sun being in the plane of the hour-circle which cuts the horizon in RAR′, and it being understood that, in the celestial sphere, there may exist a spherical triangle formed by arcs joining P the pole of the equator, S the place of the sun, and Z the zenith of the place, or the point vertically above O [see *fig.* to AZIMUTH, and imagine S to be put in place of ∗], we shall have PZ the co-latitude of the place, PS the sun's north-polar distance, and the given hour-angle at P; to find the angle at Z (= MAR′ or MAR).

In that triangle we obtain [SPHERICAL TRIGONOMETRY, formula 6],

$$\text{cotan } Z = \frac{\cos ZP \cos P - \text{cotan } PS \sin ZP}{\sin P}$$

But RB (*fig.* above) being let fall perpendicularly on OM produced if necessary, let $OB = x$, $BR = y$, $OA = x'$; then

$$\text{cotan } MAR \; (= \text{cotan } Z) = \frac{AB}{BR} = \frac{x - x'}{y}.$$

Equating these values of cotan Z, there is obtained $x' =$

$$\frac{x \sin P - y \cos ZP \cos P + y \sin ZP \text{ cotan } PS}{\sin P}$$

This equation containing three unknown quantities, the problem is indeterminate; but, since the following conditions must be satisfied, the values of x and y may be found: First, the position of R, the hour-point, must be independent of the sun's polar distance; therefore x and y must be independent of PS, which gives

$$x \sin P - y \cos ZP \cos P = 0;$$

also x' must be independent of the given hour; whence $\frac{y \sin ZP}{\sin P}$ must be considered as constant; let the constant be represented by m; then

$$y = \frac{m \sin P}{\sin ZP} \text{ and } x' = m \text{ cotan } PS.$$

From the equation for 0 we have

$$x = y \cos ZP \text{ cotan } P,$$

and substituting the value of y,

$$x = m \text{ cotan } ZP \cos P.$$

Squaring the values of x and y, and adding the results together, there is obtained, after reduction,

$$\frac{x^2}{m^2 \text{ cotan}^2 ZP} + \frac{y^2}{m^2 \text{ cosec}^2 ZP} = 1,$$

which is the equation to an ellipse, having for its semi-tranverse axis m cosec ZP, and for its semi-conjugate axis m cotan ZP.

The constant m may be taken of any magnitude at pleasure according to the intended scale of the dial; thus the ellipse may be traced. The hour-points may be found by giving to the angle P successive values, as 15°, 30°, &c., and corresponding values for the half-hours, quarter-hours, &c. in the above values of x and y.

AZOBENZIDE ($C_{24}H_{10}N_2$). A reddish-yellow crystalline body, obtained along with aniline, by the dry distillation of azoxibenzide. It is lightly soluble in water, and easily soluble in alcohol, fuses at 149° Fahrenheit, and distils without alteration at 379°.

AZOBENZOYL ($C_{42}H_{15}N_2$). An unimportant neutral solid, obtained amongst other compounds by the action of ammonia on oil of bitter almonds.

AZOERYTHRIN. [LICHENS, COLOURING MATTERS OF.]

AZOLEIC ACID. One of the acids formed by the action of nitric acid on oleic acid.

AZOLITMIN. [LICHENS, COLOURING MATTERS OF.]

AZOMARIC ACID ($C_{40}H_{22}(NO_4)_2O_8$)? A yellow, amorphous acid, obtained by acting upon resin with a large quantity of nitric acid.

AZONAPHTYLAMINE. [NAPHTHALIN.]

AZOTANE. [NITROGEN, CHLORIDE OF.]

AZOTE. [NITROGEN.]

AZOTIC ACID. [NITRIC ACID.]

AZOXIBENZIDE ($C_{24}H_{10}N_2O_2$). A yellow, crystalline, inodorous, and tasteless substance, obtained by the action of caustic potash upon an alcoholic solution of nitrobenzol.

AZULMIC ACID. This name has been applied to the brown flocculent matter which is deposited when an aqueous solution of cyanogen is exposed to light.

B

B, which occupies the second place in the Hebrew alphabet, and those derived from it, is the medial letter of the order of labials. It readily interchanges with the letters of the same organ. 1. With *v*, as *habere* Latin, *avere* Italian, to have; *habebam* Latin, *aveva* Italian, I had. In Spain, and the parts of France bordering upon Spain, the letter *b* will often be found in words which in the kindred languages prefer the *v*. This peculiarity has been marked in the following epigram by Scaliger:—

Haud temere antiquas mutat Vasconia voces
Cui nihil est aliud vivere quam bibere.

The modern Greeks pronounce the *b*, or second letter of their alphabet, like a *v*: thus βασιλεὺς, *basileus*, is pronounced by them *vasilefs*. When they write foreign words, or words of foreign origin, it is not unusual for them to express our sound of *b* by μπ (*mp*). It appears probable that the ancient Greeks pronounced the *b* more like the Spaniards and modern Greeks than we do; for they wrote the Roman names *Varro*, *Virgilius*, thus Βάῤῥων (Barron), Βιργίλιος (Birgilius). The Macedonian Greeks wrote Φίλιππος thus—Βίλιππος (Bilippus).

2. The interchange of *m* and *b* takes place very frequently, especially when they are followed by the liquids *l* or *r*. Thus *malakos* and *blaks* are two Greek nominatives, signifying soft. *Melit*, in the same language, means honey, and *blitto* signifies "I remove the honey from the comb." So *bro-tos*, the Greek for mortal, and *mor-i*, the Latin for to die, contain a common root. An interchange of a similar nature marks the difference between the Greek *molubos* or *molubdos*, lead, and the Latin *plumbum*. If an *m* in the middle of a word be followed by either of these liquids, the *m* is retained, but is strengthened by the addition of a *b*, just as a *d* inserts itself between *n* and *r*. Instances are to be found in nearly all languages: *mes-emer-ia*, mid-day, was reduced by the Greek ear to *mesembria*; the Latin *cumulare*, to heap, has been changed to the French *combler*; the Latin *numerus*, number, to the French *nombre*, &c. The Spanish language affords examples of a still greater change. Thus, if a Latin word contain the letters *min* after an accented syllable, we find in the corresponding Spanish term the syllable *bre* or *bra*: *homine* Latin, *hombre* Spanish, man; *femina* Latin, *hembra* Spanish, female; *famina* (middle-age Latin), *hambre* Spanish, hunger. This corruption arises from a previous interchange of the *n* into an *r*, as in *diaconos* Greek, deacon, *diacre* in French. The Spaniards have carried this corruption even further, by changing the Latin suffix *tudine* (*tudo* nom.) into *tumbre* or *dumbre*; *consuetudine* Latin, *costumbre* Spanish, *coutume* French, custom; *multitudine* Latin, *muchedumbre* Spanish, multitude. 3. *B* interchanges with *p*. Of this the pronunciation of the English language by the Welsh and Germans presents sufficient examples. 4. With *f*. Thus the term *life*-guards appears to have meant originally *leib*-guards, *body*-guards, from the German *leib*, body. The word was probably introduced by the Hanoverian dynasty. 5. *Du* before a vowel in the old Latin language became a *b* in the more common forms of that language. Thus, in the old writings of Rome, we find *duonus* good, *duellus* fair, *duellum* war, &c., in place of *bonus*, *bellus*, *bellum*. The Roman admiral Duilius is sometimes called Bilius; and in the same way we must explain the forms *bis* (*duis*) twice, and *viginti* (*dui-ginti*) twenty (*twain-ty* compared with thir-ty, &c.) 6. *Bi* before a vowel has taken the form of a soft *g* or *j* in several French words derived from the Latin: *cambiare* (a genuine Latin word), *changer* French; *rabies*, *rage*, French; *Dibion*, *Dijon*; so *rouge* has for its parent some derivative of *rubeo*, and *cage* is from *cavea*. 7. In some dialects of the Greek language a *b* exists (apparently as a kind of aspirate) before the initial *r*, where the other dialects omit it: as *brodon*, a rose, &c. Again *bl* and *gl* are interchanged in dialects of the same language. Thus *balanos* Greek, and *glans* Latin, are no doubt related words; as well as *blandus* Latin, signifying 'soft, mild, calm,' and *galenos* Greek, which has the same signification. For the forms of the letter B, see ALPHABET.

In the Sanskrit alphabet the letter *b* is classed in that division of the consonants called mutes, and in that subdivision of the mutes called labials. The subdivision of labials contains four letters—*p*, *ph*; *b*, *bh*; and *m*. The *p* and *ph* are called hard (*surd*) consonants; the *b* and *bh* are called soft (*sonant*); *bh* is the aspirated sonant corresponding to *ph* the aspirated surd. ('Journal of Education,' No. xvi. p. 341, &c.)

BAAL (from the root בָּעַל, *he governed* or *possessed*) means literally *lord*, *owner*; hence also *husband*. Baal, with the definite article, הַבַּעַל, *the Baal*, means the deity of the Phœnicians and Carthaginians, whose complete title seems to occur in a Maltese inscription, as מַלְקֶרֶת בַּעַל צוּר, *Malkereth Baal Tsor*, that is, *King of the City*, *Lord of Tyre*. (See 'Philosoph. Transact.' T. 54 pl. lin. 1.) The name Malkereth is a contraction of מֶלֶךְ קֶרֶת, king of the city. Hence it appears likely that Baal and Moloch are names of the same idol. Baal was the god of the Sun, as Astarte was of the Moon. The crue worship of Baal, together with that of Astarte, was practised by the Egyptians and Assyrians, and was frequently introduced among the Israelites, especially at Samaria. As the Greeks, Germans, and other nations frequently form the names of men by compounding them with the names of God (for example, *Gottlieb*, *Gotthold*, *Fürchtegott*, Θεόφιλος, Θεόδωρος, Τιμόθεος, &c.), so the Phœnicians and Carthaginians frequently formed names by composition with *Baal*, as Ethbaal (אֶתְבַּעַל), *with Baal*, the name of a king of the Sidonians (1 Kings xvi. 31), whom Josephus calls Ἰθόβαλος and Εἰθώβαλος, from אִתּוֹ בַּעַל, that is, *with him* Baal; *Jerubaal*, יְרֻבַּעַל, that is, *Baal will behold it*. Hannibal is written in Punic inscriptions חַנִּבַּעַל, that is *grace of Baal*; Hasdrubal עֲזְרֻבַּעַל, that is, *help of Baal*.

In Hebrew also many names of cities occur, compounded with Baal, from the idol so called; as Baal-Gad, Baal-Hammon, Baal-Thamar, &c. Balbec in like manner signifies the city of Baal.

The statues erected to Baal were called Baalim, or rather B'alim, בְּעָלִים. The temples and altars of Baal were chiefly built on the tops of hills under trees and also on the roofs of houses. In the sculptures discovered by Layard at Nimroud, representations of the symbolic tree of Baal—corresponding to the grove of the Scriptures—are very numerous. So also are representations of Baal himself, who, in a bas-relief from the south-west ruins of Nimroud, is figured in a walking attitude, raising an axe in one hand, and grasping an object resembling the thunderbolt placed by Greek sculptors in the hand of Zeus in the other; he is also represented in front of a circle, the radiating lines of which seem to typify the sun's rays; but very frequently only the symbol of the deity (the circle and radiating lines) occurs above the head of the Assyrian king. Very similar symbols are frequently met with over the doorways of Egyptian temples. Pliny says that obelisks were regarded as typical of the solar rays, and dedicated to Baal or the Sun: and it has been suggested that the image of gold set up by Nebuchadnezzar (Dan. iii. 1), was really such an obelisk. The proportions of the image, threescore cubits high and six wide, are evidently unsuitable for an image of a man; while, as Mr. Bonomi ('Nineveh,' p. 450) has pointed out, they "agree perfectly with those of an obelisk, most of the Egyptian obelisks being about ten times the width of the base in height."—Indeed, there is still standing among the ruins of Karnak, in Egypt, an obelisk of a single block of granite 90 feet high by 9 feet wide—the dimensions of the image of Nebuchadnezzar, "and we have only to fancy that monument to be covered with plates of gold, to have present to the imagination the image of the plain of Dura."

The worship of Baal gave employment to a numerous priesthood, who burned incense, sacrificed children, danced round the altar, and if their prayers were not speedily heard, cut themselves with knives and lancets till the blood gushed out upon them. By this self-chastisement, the priests expected to excite the compassion of Baal, and thus to obtain the object of their prayers.

The general character of Asiatic idolatry renders it likely that Baal meant originally the true Lord of the universe, and that his worship degenerated into the worship of a powerful body in the material world. Sanchoniathon states that the Phœnicians worshipped the sun as μόνον οὐρανοῦ κύριον, "the only Lord of heaven," called Βεελσάμην *Beelsamen* (that is, בַּעַל שְׁמַיִן, Lord of heaven); and that this Beelsamen was the Greek Ζεὺς, *Zeus*. In the Septuagint, Baal is called Ἡρακλῆς, Hercules, called in the Phœnician language אוֹר־כֹּל, *Or-cul*, that is, light of all. Some mythologists have asserted that Baal was Saturn (compare Servius 'ad Æn.' i. 729); others have considered Baal to be the planet Jupiter. A supreme idol might easily be compared with those of other nations; hence arose this variety of opinions.

The statement of Herodian (v. 5; and Capitol. 'vit. Macrini,' 9) that the Phœnicians and Syrians worshipped the sun, is confirmed by the occurrence of the name of Baal together with that of the sun on Carthaginian coins and Palmyrene inscriptions, as בַּעַל שֶׁמֶשׁ, בַּעַל שָׁמַיִם, בַּעַל חַמָּן.

The name of Baal occurs frequently with epithets, as Baal-B'rith, (בַּעַל בְּרִית) that is, lord of confederacy, or God of treaties, like the Greek Ζεὺς ὅρκιος, and Latin, Deus Fidius, Judges viii. 33; ix. 4.

Beelzebub, (בַּעַל זְבוּב, that is, *lord of flies*,) corresponds to the Greek Ζεὺς ἀπόμυιος, μυίαγρος, Zeus the fly-chaser (Pausan. v. 14): compare Hercules μυίαγρος. He had a temple at Ekron, 2 Kings i. 2.

Baal Peor (בַּעַל פְּעוֹר), Numbers xxv. 1—9, is the Priapus worshipped by the Moabites on Mount Peor, from פָּעַר, *distendit.*

To worship Baal signifies frequently, in the phraseology of the Jewish writers of the middle ages, to practise the rites of the Christian religion. Rabbi Joseph Ben Josua Ben Meir tells us, in his 'Chronicles,' that Clovis forsook his God and worshipped Baal, and that a high place was built at Paris for Baal Dionysius, that is, the Cathedral of St. Denis. Rabbi Joseph informs us also that the Friar Vincent, of the sect of *Baal* Dominic, that is, the Dominican Friar, was a Satan unto the Jews in Spain about A.D. 1430.

(For further information on Baal we refer to the commentators on Judges, Kings, Chronicles, Isaiah, Jeremiah, Hosea; J. E. Elsner, *De Ritu Baalem exorandi*, Ling. 1723; Fromman, *De Cultu Deorum ex Onomothesia illustri*, Altorf, 4to et seq. 1745; Müntur, *Religion der Carthager*, Kopenhagen, 8vo, 1821; Serv. ad Æn. i. 729; Lingua Punica Deus Bal dicitur, Isidor. *Origin.* viii. 11; Creutzer's *Symbolik*, ii. 266, &c.; Eusebii *Præparatio evangelica*, i. 10; *Fragmenta* Sanchoniathon, ed. BA'BYLON, HISTORY. The Babylonians belonged to the Semitic race of nations; their language was an Aramaic dialect, and differed little from the common Syriac. The existence of their city and empire can be traced back to an epoch of the remotest antiquity. In the tenth chapter of Genesis, Babel is mentioned as having formed part of the dominions of Nimrod, and Josephus ('Ant. Jud.' i. 6) calls him the founder of the town of Babylon. The building of the city and tower of Babel, and the subsequent confusion of tongues (Genes. xi. 1—9) are among the earliest facts in the history of mankind which we find recorded in the Hebrew scriptures. We learn from Josephus, Eusebius, and the Armenian chronicle of Moses of Chorene, that the Chaldæans had a similar tradition to account for the origin of the different languages now spoken by men; but it is difficult to determine whether this tradition was independent of, or whether it was derived from, that recorded in the book of Genesis. Diodorus (ii. c. 7), on the authority of Ctesias, attributes the foundation of the city of Babylon to the celebrated queen Semiramis, and when we read of immense numbers of workmen (two hundred myriads) from all parts of her empire, whom she employed in the execution of her design, we are almost involuntarily reminded of that part of the Hebrew narrative, which describes "the children of men" building the tower, until "the Lord scattered them abroad from thence upon the face of all the earth, and they left off to build the city." ('Genes.' xi. 8.) The epoch at which the city and the tower were founded cannot be determined with precision; according to the calculation usually adopted, it happened about two hundred years after the deluge.

Herodotus (i. c. 184) says that the building of Babylon was the work of several successive sovereigns; but among them he distinguishes the two queens, Semiramis and Nitocris, to whom the city was indebted for extensive embankments along the Euphrates, and for many other improvements. According to Diodorus (ii. 1, &c.), the Assyrian king Ninus, assisted by an Arabian chief, Ariæus, conquered and killed the then reigning king of Babylon, and made himself master of his dominions; the town of Babylon did not then exist, but there were other flourishing towns in the country. His wife Semiramis, who succeeded him, founded Babylon, and made it her residence, until which time Nineveh had been the capital of the empire. [NINEVEH, in GEOG. DIV.] She enclosed it with brick walls of great height and thickness, joined the two banks of the river by a bridge (besides a subterraneous passage or tunnel), built a royal palace on each side, and erected in the middle of the town a high temple in honour of the god Belus. This is usually supposed to have happened about the year 2000 before our era.

Respecting the history of Babylon under the successors of Semiramis we are left in almost entire ignorance. From one of the inscriptions found at Nineveh (many of which are now in the British Museum), Sir W. Rawlinson has deciphered much of the history of Sardanapalus (which he writes As-sar-adun-pul); but it only contains an account of his military expeditions up to the thirty-first year of his reign, against peoples and countries many of which it is not easy to identify. After the overthrow of the Assyrian monarchy and the death of Sardanapalus (888 B.C.), Belysis, a skilful priest and astrologer, assumed the government of the Babylonian state. (Diodor. ii. c. 24, &c.) He was succeeded on the throne by his son Nabonassar, and the regal dignity became hereditary in his family. The era of Nabonassar, beginning the 26th of February, 747 B.C., is supposed to have been so called, because the Chaldæans, during the reign of this king, might have begun to avail themselves in their astronomical observations of a moveable solar year, which they might either have invented themselves, or received from the Ægyptians. This era was, however, never used in common life, and for all ordinary practical purposes the Chaldæans counted by lunar years. (See Ideler, 'Lehrbuch der Chronologie,' p. 89.)

We know very little of the immediate successors of Nabonassar. Sharpe and Oppert give lists of kings to the taking of Babylon, but the lists do not agree either in the number or the names. Merodach-Baladan, or Berodach-Baladan, the son of Baladan, is mentioned in the Old Testament (2 Kings, xx. 12, 13; Isaiah, xxxix. 1) as being on friendly terms with Hezekiah, the king of Judah, at a time when both dreaded the ascendancy of Sennacherib, the king of Assyria. Soon afterwards the Assyrian monarch, Esarhaddon, incorporated Babylon into his empire. But towards the latter part of the 7th century before our æra, we again find Babylon under Nabopolassar, the Ahasuerus of Tobit (627—604 B.C.), an independent and powerful state, and as such it continued till the period of its destruction by Cyrus. In the battle of Circesium (604) the independence of the Babylonian state was vindicated against the ambitious designs of Nekos, king of Egypt, who had sent an army to conquer it. Babylon had its bright epoch in the reign of Nebuchadnezzar, or Nabuchodonosor (604—561 B.C.), who increased his dominions by the conquest of Palestine, Tyrus, and Jerusalem (2 Kings xxv. 1; 2 Chron. xxxvi. 17), and added to the fortifications as well as to the ornaments of the city of Babylon. He subdued the Idumæans (the Edomites) and the Ammonites, and his empire extended from the Caucasian mountains to the African desert. It is surprising that the name of Nebuchadnezzar is apparently unknown to Herodotus, especially as we are told by Josephus, that it was familiar to Megasthenes and other Greek historians. The queen Nitocris, mentioned by Herodotus (i. 183), who contributed much to the improvement of the town of Babylon, is supposed to have been the wife of Nebuchadnezzar. After the death of Nebuchadnezzar, the empire began rapidly to fall into decay. His son Evilmerodach (561—559) permitted king Joacim, of Juda, to return home out of his captivity at Babylon, whither Nebuchadnezzar had brought him. Evilmerodach was killed in the second year of his reign by his brother-in-law Neriglissar, who occupied the throne during the four succeeding years (559—555). He was followed by his youthful son Laborosoarchod, or Labassoarascus, who had been only nine months on the throne when a conspiracy broke out in which he was dethroned and killed. Nabonnedus (the Labynetus of Herodotus, i. 74—77, and the Belshazzar, or Balthasar, of the Old Testament) followed him, and reigned seventeen years (555—538 B.C.), at the end of which he was attacked and defeated by Cyrus ('Dan.' v. 30, 31), and Babylon became subject to the Persian empire.

Cyrus did no injury to the town of Babylon: on the contrary, he made it his winter-residence, and the third capital town of his kingdom, after Susa and Ecbatana. But in consequence of a revolt under Darius I., the walls and gateways of the town were broken down, and the population soon decreased in such a degree that a supply of women from the surrounding country became requisite. (Herod. iii. 159.) Xerxes carried away the golden statue of Belus (Zeus, Herod. i. 183), and Alexander the Great found the temple of that deity in ruins. (Arrian. 'Exp. Alex.' vii. 17.) Soon afterwards Seleucus founded the town of Seleucia in the neighbourhood of Babylon, which further contributed to the decrease of the latter. At the time of Diodorus and Strabo, the greater part of Babylon lay in ruins, and there were cornfields within its ancient precincts. Curtius says, that at his time only one-fourth of the town was inhabited: Philo and Josephus observe, that a considerable proportion of the inhabitants were Jews. [NINEVEH, in GEOG. DIV.]

BABYLONIAN ARCHITECTURE. [NINEVEH, ARCHITECTURE OF.]

BACCHANALIA. [DIONYSIA.]

BACHELOR, an unmarried man; a word, as Johnson says with truth, of uncertain etymology, for which many fanciful and absurd derivations have been given, the most absurd being those from βάκηλος foolish; *bacillus*, a little stick; and *bacca lauri*, the berry of the laurel. Ducange has collected various meanings of the word, of which the following deserve mention :—

1st. The term baccalarii was applied to those who held, possessed, and cultivated certain lands called baccalaria (which Ducange supposes to be a corruption of vasseleria, the fee belonging to an inferior vassallus); frequent mention of these tenants and their lands is made in old charters.

2nd. By the expression baccalarii are described ecclesiastics of a lower dignity and grade than the other members of a monastery; the term frequently occurs in this sense in monastic writings and records; thus, for example, in one old abbatial history we read, "Finita Missa, in exitu ecclesiæ incipitur Antiphona O Martini; sequitur Litania et debet dici a duobus baccalariis;" and in an old charter of amortization, in 1408, occurs the following: "Les chappelains et les bacheliers de l'église collégial de Nostre Dame de Mirebeau."

3rd. The word was used by later writers to distinguish those who, being members of the military order, were inferior to bannerets, not having as yet, levé bannière, either from want of age or from poverty. The word in this sense is often referred to in the poems of the Troubadours.

4th. Any young unmarried person, whether male or female, was called bachelier and bachelette. From ancient documents cited by Ducange, it would appear that it was not unusual to impose a tax upon unmarried men. One in 1223 runs "Homo qui est bachalarius, quamdiu in illo statu erit et hospitium tenebit, reddit annuatim quinque solidos de censa."

5th. The term was, in analogy to the above, appropriated by learned bodies, such as universities and academies, to designate those who, like the military baccalarii, were aiming at the higher grades of their profession, "ad doctoratum aspirantes;" see Ducange *sub verbo* baccalarii; and for more information on the etymology of the word the reader is referred to Ménage's 'Etymological Dictionary of the French Language,' and to Selden's Treatise—'History of Titles,' 2nd part, c. 3, s. 24.

The legislation of the Romans placed unmarried persons (cælibes) under certain disabilities, the chief of which were contained in the Lex Julia et Papia Poppæa. But even before that time, according to Livy (lxv. 15), they had been placed in an inferior position to the married citizens, and separated into four urban tribes, an inferiority Cicero (3 De Legibus, 3, 7) alludes to in the words "Censores prolem describunto, cælibes esse prohibento." The original Lex was simply called Julia, and was passed 18 B.C. (Dion Cassius, liv. 16.) The Lex Papia et Poppæa, which was intended as an amendment and supplement to the Lex Julia, was passed A.D. 9; and both these leges seem to have been considered as one, being often referred to under the title of the Lex Julia et Papia Poppæa. One object of the Lex was to encourage marriage. An unmarried person (cælebs), who was in other respects qualified to take a legacy, was incapacitated by this Lex, unless he or she married within one hundred days. (Ulpian, 'Frag.' xvii. 1.) The law was the same if the whole property (hereditas) was left to a cælebs. (Gaius, ii. 111, 144, 286.) It was the opinion of the lawyers, that though a cælebs could not take directly under a testament, a cælebs could take by way of fidei commissum, or trust; but the Senatûs-consultum Pegasianum, which was passed in the time of Vespasian, rendered a cælebs equally incapable of taking anything by way of fidei commissum. (Gaius, ii. 286.) A testamentary gift, which failed to take effect because the heres or legatee was a cælebs, was called Caducum (and the word was applied to other cases also), "something which failed or dropped." In the first instance, such a gift came to those among the heredes who had children; and if the heredes had no children, it came to those of the legatees who had children. If there were no such claimants, the Caducum came to the public treasury (ærarium). But by a constitution of the emperor Antoninus Caracalla, the Caducum came to the Fiscus, or Imperial treasury, instead of the public treasury; the rights of children and parents, however, were reserved. (Ulpian, 'Frag.,' xvii.) An unmarried man who had attained the age of sixty, and an unmarried woman who had attained the age of fifty, were not subjected to the penalties of the Lex Julia et Papia Poppæa as to celibacy, but a Senatûs-consultum Pernicianum (Persicianum), passed in the time of Tiberius, extended the penalties to unmarried persons of both sexes who were above sixty and fifty years old respectively, and it made them for ever subject to the incapacities. However, a Senatûs-consultum Claudianum, passed in the time of Claudius, mitigated the severity of the Pernicianum by substituting a new clause in the place of the old one, enacting that there should be no penalties imposed on men who, being above the age of sixty, married wives under fifty years, for from those unions there was a fair prospect of issue. (Ulpian, 'Frag.' xvi.; Suetonius, 'Claudius,' c. 23.)

The Lex Julia et Papia Poppæa also imposed incapacities on *orbi*, that is, married persons who had no children from the age of twenty-five to sixty for a man, and twenty to fifty for a woman. Childless persons who came within the terms of the Lex lost one-half of any hereditas or legacy; and what they could not take became Caducum. The Lex also gave direct advantages to persons who had children. The original object of this Roman law was perhaps only to encourage marriage, but it was afterwards used as a means of raising revenue.

In the preceding exposition of the Lex Julia et Papia Poppæa, it has been assumed that the provisions above enumerated applied both to males and females. The word *cælebs*, indeed, which may be explained as one "qui est sine conjugio sive aliquando sive nunquam matrimonium inserit," seems to be applied only to males, and the Latin term for an unmarried woman is *vidua*, which means any woman who has not a husband. But the expression of Ulpian ('Frag.' xvi. 3), "Qui intra sexagesimum vel quæ intra quinquagesimum annum neutri legi (the Julia or Papia Poppæa) paruerit," &c., shows that the provisions applied both to males and females. The word cælebs would not be used in the enactments of the Lex, but the phrase would be 'Qui Quæve,' &c. That the Lex applied to women also, appears from other evidence. ('Cod.' viii. tit. 57.) Under the republic there were also penalties on celibacy, and legal inducements to marriage, which are mentioned in the speech which Dion Cassius (lvi. 2—9) puts into the mouth of Augustus. Julius Cæsar, in the division of the Campanian lands, gave allotments only to those who had three children or more. (Dion Cass. xxxviii. 7; Appian, 'Bell. Civil.' ii. 10.) Hence in later times we find the celebrated Jus trium, quatuor et quinque liberorum, which was a consequence of the enactments above referred to, whose importance is abundantly testified in the old inscriptions which have survived to our day. For a lengthened commentary on this law, see the work of M. Vertranius Maurus, in Otto's 'Thesaurus Juris Romani,' iii. p. 967. The censors also are said to have had the power of imposing a penalty called Æs Uxorium, "wife-money," on men who were unmarried. (Festus, *voce* 'Uxorium.') From the earliest times it had always been a part of the Roman policy to encourage the procreation of children; the object of the English law imposing extraordinary payments on bachelors, and relieving to a certain extent married persons with children, was apparently to raise money, though a certain vague notion that marriage should be encouraged seems also to have occurred to the law-maker. A constitution of Constantine ('Cod.' viii. tit. 58) relieved both unmarried men and women from the penalties imposed on cælibes and orbi, and placed them on the same footing as married persons. This change was made to favour the Christians, many of whom abstained from marriage from religious motives.

Not only bachelors, but widowers have been unequally taxed in this country, and there is more than one instance, within the last sixty years, in which persons have been favoured by special exemptions, or have been charged less on account of the number of their children. In 1695 an Act was passed (6 & 7 Will. III. c. 6) entituled "An Act for granting to his Majesty certain rates and duties upon marriages, births, and burials, and upon bachelors and widowers, for the term of five years, for carrying on the war against France with vigour."

Bachelors above the age of twenty-five, and widowers without children, paid 1*s.* yearly, and further according to their rank. Thus, for a bachelor duke the tax was 12*l.*, and other ranks in proportion. An esquire was charged 35*s.* a year, and a person of the rank of gentleman 5*s.* Persons possessed of real estate of 50*l.* a year, or personal property of 500*l.* value paid 5*s.* A supplementary Act was passed two or three years afterwards (9 Will. III. c. 32), to prevent frauds in the collection of the taxes imposed by the former Act, but the tax was allowed to expire in 1706. In 1785, when Mr. Pitt proposed a tax on female servants, he exempted persons who kept only one servant, and who had two or more lawful children or grandchildren under the age of 14 living in the house with them. But to make up for the deficiency, he proposed that the tax on servants should be higher for bachelors than for others; and he stated that the idea of this tax was borrowed from Mr. Fox. This differential rate, though reduced in amount by 4 Geo. IV. c. 11, has been continued to the present time, and the number of servants charged at the higher rate in 1842 was 11,831, or rather more than one-tenth of the whole number charged. In 1853, the number charged amounted only to 11,417, the relative proportions being about the same. Roman Catholic clergymen are exempt from additional duty, 4 & 5 Will. IV., c. 73, s. 4; and by Schedule I of 48 Geo. III., c. 55, incorporated into 52 Geo. III. c. 93, the unmarried daughters of any person are exempted from the tax upon hair-powder. When the income-tax was imposed by Mr. Pitt in 1798, deductions were allowed on account of children, and an abatement was made of 5 per cent. to a person with children, when the income was above 60*l.* and under 400*l.*; and other rates of abatement were allowed according to the amount of income and the number of children: this indulgence extended to incomes of 5000*l.* a year and upwards, but these deductions have not been continued by recent legislation.

There does not appear to be a tax on bachelors in any country in Europe. In the city of Frankfort an income-tax is paid by journeymen who work in the city, "if they are foreigners, and not married."

BACHELOR OF ARTS. [ARTS, DEGREES IN.]

BACKGAMMON, a game played by two persons with dice, upon a table divided into two parts, upon which there are twelve points of one colour and twelve of another. Dr. Henry ('Hist. of Eng.' 4to, 1774, vol. ii. p. 601), speaking of the end of the Anglo-Saxon time, says, "The game of backgammon, it is pretended, was invented in Wales in this period, and derives its name from the two Welsh words *bach*, little, and *cammon*, battle." He refers for this information to the glossary at the end of Wotton's 'Leges Wallicæ,' p. 583. Bishop Kennett, however, among his manuscript collections, gives us a more probable etymology of backgammon from bæc, back or backward, and the Anglo-Saxon ʒamen, a game, sport, or play. Strutt, in his 'Sports and Pastimes,' adopts this derivation, and gives a representation of the game in the 13th century, from Harl. MSS. No. 152. The name however was changed by the Normans for that of *Tables*, derived immediately from the French, under which it is mentioned by Shakspere ('Love's Labour's Lost,' Act. v. sc. 2), Burton ('Anatomy of Melancholy,' part ii. § 2, No. 4), and others. Somewhat later, it acquired also the name of *tric-trac*, or *tick-tack*, a term also used by Shakspere in 'Measure for Measure.' After centuries of disuse, the original Saxon name re-appeared, and for a long time the game has been only known as backgammon.

Hoyle, in a short 'Treatise on Backgammon,' has treated amply of its practice, and given full directions how to play the different chances, with observations, hints, and cautions to be attended to. The table is divided into twenty-four points of alternate colours, and the game is played with fifteen men of different colours, and a pair of dice for each player. The men are disposed in a settled order on the board, and the game consists in bringing the men home,—that is, into the division of six nearest the player's left hand, the moves being made according to the numbers thrown by each player with the dice, the throws being taken alternately. Where a single man is left on a point, it may be lifted by the adversary if the throw enables him to hit it. When all the men are home, they are taken off according to the throw of the dice, and the party first clearing off all his men is the winner. If this is done before the adversary has all his men home, it is a gammon, which counts double; if while he has one man or more in his antagonist's home, it is a back-gammon, which counts as three. Hoyle gives the following as the laws of backgammon: 1. If you take a man from any point, that man must be played; the same must be done if two men are taken from it. 2. You are not understood to have played any man till you have placed him upon a point and quitted him. 3. If you play with fourteen men only, there is no penalty attending it, because by playing with a less number than you are entitled to you play to a disadvantage, by not having the additional man to make up your tables. 4. If you bear any number of men, before you entered a man taken up, and which consequently you were obliged to enter, such men, so borne, must be entered again in your adversary's tables, as well as the man taken up. 5. If you have mistaken your throw and played it, and if your adversary has thrown, it is not in your or his choice to alter it, unless both parties agree to it.

Strutt also says, "At the commencement of the last century backgammon was a very favourite amusement, and pursued at leisure hours by most persons of opulence, and especially by the clergy, which occasioned Dean Swift, when writing to a friend of his in the country, sarcastically to ask the following question: 'In what esteem are you with the vicar of the parish; can you play with him at backgammon?'"

BACON. Considered as an article of food, bacon gives rise to a considerable commerce. Whether of superior or inferior quality, it is prepared from pork by a process in which salt, heat, and smoke are employed. Good bacon has a thin rind; the fat has a firm consistency and a reddish tinge; and the lean adheres strongly to the bone. There is no other country in Europe in which the working-classes are so particular in the quality of the bacon eaten by them, and pay for it at so high a price, as in England.

There are no means of ascertaining the quantity of bacon made and sold in the country. That which we import is mixed up in the Board of Trade returns with hams. In the three years ending with 1858, the average quantity of bacon and hams imported was 312,000 cwts. annually.

BACTRIAN COINS. A sketch of the history of Bactria, or Bactriana (now Bokhara), is given under AFGHANISTAN, in the GEOGRAPHICAL DIVISION of the ENGLISH CYCLOPÆDIA. The Persian province of Aria was bounded partly on the north and to a greater extent on the east, by Bactria. The river Oxus was the boundary between Bactria and Sogdiana, which lay to the east of Bactria, and was possessed by the Greek kings of this province. (Strabo, p. 517.) The northern boundary of Bactria was naturally indefinite, and the western was Margiana. These limits, which mark the extent of Bactria as a province or satrapy, do not of course correspond with the more extended limits of the Greek Bactrian kingdom. The province of Bactria was a territory of great extent, partly barren and waste, but in many parts of great fertility, watered by the Oxus and its tributary streams, and peopled by a brave and hardy race, who were reckoned amongst the best soldiers in the service of Persia after Bactria became a Persian province. The chief city was Bactra, called also Zariaspa, situated on the Bactros, one of the tributary rivers of the Oxus. Of Bactra little is known prior to its subjugation by the Macedonians under Alexander the Great. The account of an expedition against it by Osymandyas the Egyptian, merits no confidence; and those of Ninus and Semiramis perhaps not much more. According to Herodotus, Cyrus, having defeated Crœsus, intended to invade Bactria; and (according to Ctesias) after a drawn battle, the Bactrians voluntarily surrendered themselves to him. In the reign of Darius I. the Bactrians paid a tribute to that monarch of 360 talents. In the time of Xerxes there were Bactrians in the army which he led against Greece, who were under the command of Hystaspes, a son of Darius by Atossa, a daughter of Cyrus. The province continued to be governed by the satraps of Persia down to the time of Darius Codomannus. In the final overthrow of that king by Alexander the Great, at the battle of Arbela or Gaugamela, there was a body of Bactrians in his service who were under the command of Bessus, the satrap of Bactria; they were stationed in the left wing, and behaved with great bravery. After the conquest of Bactria by Alexander he appointed Artabazus, a Persian, as governor, with Macedonian garrisons in the towns. Shortly afterwards they were attacked by the Scythians, joined by the people of Sogdiana and some Bactrians, the whole under the command of Spitamenes, who slew the garrisons and fortified themselves. They were attacked in their turn by Alexander, who stormed seven of their cities, and among them Cyropolis, the strongest of the whole. His next step was to build a city, which he walled in twenty days, and gave to his Greek mercenaries and to such of the Macedonians as were unfit from age or wounds for longer service. Such was the foundation of the Greek colony of Bactria, to which volunteers from the neighbouring countries were admitted. This, however, was not the earliest settlement of Greeks in Bactria; for the first Darius transplanted there a number of Greeks from Barce, in Africa (Herod. iv. 204); and the Branchidæ also, from Ionia, were planted here by Xerxes I. (Strabo, p. 517.)

After the death of Alexander, Bactria remained for fifty years a province of Persia, with which it was united by Seleucus Nicator, between B.C. 312 and 301. When Seleucus became king of Syria, Bactria became a dependency of the great Syrian empire of the Seleucidae. During the reign of Antiochus Theus (B.C. 262-247) Bactria was constituted an independent kingdom by the governor Theodotus or Diodotus, who was a Greek by birth, and it continued so under his successors for several centuries. The history of the Bactrian kings of Greek descent is not given by any of the extant Greek or Roman historians. It may have been noticed in Arrian's lost history of the successors of Alexander. A few names mentioned by the ancient historians, or discovered on some rare coins, and the fact related by the Chinese annalists that this Greek kingdom was overthrown by the Scythians, was all we knew of it. In spite of the barrenness of materials, the learned Bayer undertook to write his 'Historia Regni Graecorum Bactriana,' Petersburgh, 1738, a book more valuable for what the author says on things connected with Bactria, than for information on Bactria itself. Bactrian coins were then so rare, that the discovery of two gold coins towards the end of the past century created a great sensation in Europe, and the acquisition of the names of two kings was considered a valuable addition to our knowledge of Bactrian history. Nobody expected that Bactrian coins would be found in such quantities as to be sold by the measure and for little more than their intrinsic value. This was actually the case not many years back in some places in India and Afghanistan, though only with the copper coins. In the beginning of this century the late Colonel Tod made a collection of coins during his long residence in India, of which several are of high interest for the history of Bactria. A description of them was given with engravings in the first volume of the Transactions of the Royal Asiatic Society, 1824. Two of these coins bore the names of Apollodotus and of Menander, both Bactrian kings. Their historical value, says Wilson, is undiminished, but nothing is calculated to exhibit the rapid progress of numismatic discovery in respect to Bactrian coins more strikingly than the diminution of their value as objects of rarity within the last twelve years. Instead of only two medals, the cabinets of Paris and London now possess two thousand of the coins of Menander and Apollodotus, of silver and copper, of a great variety of types, and mostly in excellent preservation. The country on both sides of the Indus and north of the Hindu Koosh having been explored with a view of searching for coins, great discoveries were made. Generals Ventura, Alard, and Court, Dr. Swiney, James Prinsep, Sir Alexander Burnes, Masson, and many others, mostly British residents in India, have made collections of Bactrian coins, which enabled us to make out a complete series of Bactrian kings, of Greek and barbaric descent.

The following lists of the Greek kings of Bactria have been drawn up by Professor Wilson and by Mr. H. T. Prinsep, the brother of the late Mr. James Prinsep.

B.C.	WILSON.	B.C.	PRINSEP.
256.	Theodotus I.	256.	Theodotus I.
240.	Theodotus II.	240.	Theodotus II.
220.	Euthydemus.	220.	Euthydemus.
190.	Demetrius.	190.	Demetrius.
181.	Eukratides.	178.	Eukratides.
147.	Heliokles.	155.	Heliocles.
147.	Lysias.	150.	Antimachus.
135.	Amyntas.	190.	Agathocles.
	Agathoclea.	195.	Pantaleon.
140.	Antimachus.	155.	Menander.
130.	Philoxenus.	135.	Apollodotus.
135.	Antialkides.		Diomedes.
125.	Archebius.		Zoilus.
126.	Menander.		Hippostratus.
110.	Apollodotus.		Straton.
100.	Diomedes.		Dionysius.
98.	Hermaeus.		Nicias.
135.	Agathocles.	120.	Hermaeus.
120.	Pantaleon.		

According to these lists, several kings reigned at the same time, or at least several persons acted as independent sovereigns and coined money.

Besides the kings placed in Mr. Prinsep's list there is still a small number of others, namely, Antimachus, Archebius, Antialkides, Lysias, Philoxenus, and Amyntas, who appear to have been governors in Herat and Southern Bactria, and to have occasionally assumed the titles and prerogatives of kings. Only two Bactrian gold coins of the Greek kings are known, one of Diodotus and one of Euthydemus; all the others we know of are of silver, of billon, or of copper.

Hermaeus, the last king of the series, is supposed to have been overpowered by Azes, a Scythian, who, as it appears, conquered these countries in company with Maues. Coins of these princes, and of their successor Azilides, are frequent. They have the Greek and Arianian inscriptions. It appears that these Scythians remained in possession of the country about thirty years, from 90 to 60 B.C.

Under the term Bactrian coins are understood in this article only such medals as were struck by kings of either Greek or barbaric descent who ruled over the ancient kingdom of Bactria or parts of it; but not coins of Hindu, Afghan, or foreign Mohammedan princes who reigned at Kabool and other places in Afghanistan. The Greek coins may be divided, with respect to their inscriptions, into pure Greek and bilingual coins. The first class comprehends the names of five kings, Theodotus I., Theodotus II., Euthydemus, Demetrius, and Eucratides, who ascended the throne in B.C. 181, and perhaps reigned as long as B.C. 155. Of Theodotus I. two coins are known. One, a gold medal, was bought at the fair of Nishni-Novgorod in Russia, and is now in the Imperial Cabinet of Paris. It corresponds in weight and style with the gold coins of Antiochus II., and the portrait bears so close a resemblance to that of Antiochus, that it is supposed the artist copied

Euthydémus. (Weight 187 grains.)

Eucrátides I.* (Weight 257 grains.)

BACTRIAN COINS OF THE GREEK KINGS.

the head of that prince. The obverse has the head of Theodotus. The reverse has a naked figure of Jupiter erect, with his back to the spectator, and turned to the left; he is in the act of hurling his thunderbolt from his right arm raised, whilst his left arm extended bears the ægis: on one side, in the field of the coin, is a crown, and at the foot of the figure an eagle. The legend on each margin of the reverse is ΒΑΣΙΛΕΩΣ ΔΙΓΔ°Τ°Υ, perfectly distinct. The second coin is a silver tetradrachm, presented by Sir Alexander Burnes to the British Museum, where there are also many coins belonging to the other Greek kings of Bactria.

The bilingual class of Bactrian coins begins with Heliocles, who reigned about B.C. 147, but bilingual inscriptions are also found on the square copper coins of his predecessor Eucratides. The two languages are Greek and Prakrit, a Hindu dialect written with particular characters forming the Arian or Arianian alphabet. The oldest bilingual coins are all square, the barbaric inscriptions having been adopted together with the barbaric shape, but the later coins are both square and round. Fourteen kings with Greek names are ascribed to this class, the last of whom is Pantaleon, who reigned about B.C. 120. The Greek letters on these coins are nail-headed; the design is generally good, on some very fine, and probably done by Greek artists; but there are also many of apparently barbaric execution, and in the whole the appearance of Eastern emblems of royalty, and different Indian animals and other figures, betrays the decline of Greek civilisation; and, in addition, the title Basileus is translated by Maharajasa. Among the animals, the elephant and elephant's head, which we find on the coins of Demetrius, Menander, Apollodotus, Lycias, and Heliocles, and the humped bull on the coins of Philoxenus, Diomedes and several other kings, are supposed to indicate dominion in India. The wild horse, however, and the double-humped camel are believed to have exclusive reference to Bactria. Barbaric dynasties reigned over Bactria from the end of the second century before Christ.

The coins of the Scythic princes are exclusively of gold and silver, and bilingual—a proof that Greek civilisation, although on its decline, had still some influence upon the people, as was the case in Parthia under the Arsacidae. There are also many Sassanian coins found in Afghanistan; a fact by no means extraordinary, as the power of the Sassanians in Persia extended occasionally as far as the Indus, so that those Scythian kings were not always independent, but paid tribute to the Persians. The prince of Iskardo, in the upper valley of the Indus, pretends to be descended from Alexander. As the Greek power in Bactria was maintained in some parts of the Hindu Koosh after the Scythian conquest, the principality of Iskardo may be a remnant of the Bactro-Greek empire, and a closer investigation into the history of Iskardo and the whole upper valley of the Indus would perhaps lead to interesting results.

The obscurity prevailing in the history and chronology of Bactria has of course an influence upon Bactrian numismatics, and one cannot be surprised at seeing the principal writers on these subjects at variance on essential points.

Thomas, 1858.)

BA'GNIO, a word derived from the Italian *bagno,* which means a bath, and also a bathing-house. It has been applied, by the Europeans trading with the Levant, to the prisons in which the slaves or convicts who are made to work in the docks and at other public works in Constantinople, Tunis, and other cities of Turkey or Barbary, are shut up for the night. The French likewise call *bagne* the house of detention, where they keep their galley-slaves, at Toulon and Brest. Bagnio, in English, has been used as synonymous with brothel.

BAGPIPE, a musical instrument of the pneumatic kind, still well known in Scotch regiments. It is described by Grassineau as consisting of a leathern bag, inflated by a port-vent fixed in it, which has a valve; and of three pipes, the first and the second called the *great* and the *little drone,* each giving but one note, the third, a kind of oboe, having eight ventages or holes, on which the tune is played by the fingers. The wind is communicated to the pipes by compressing the bag under the arm, the mouth piece of each pipe being fixed in the bag. The compass of this instrument is three octaves.

The *bagpipe,* or something nearly similar to it, was in use among the ancients. Blanchinus gives a figure of it under the name of *tibia utricularis,* though this is not precisely the same as the modern instrument. Luscinius, in his 'Musurgia' (1536), has a woodcut of it, whence it appears that the bagpipe in his time was in all respects the same as in ours. Indeed, it is mentioned, though not described, by Chaucer, who says of his miller—

"A baggepipe wel coude he blowe and soune;

and this, we are told in the same prologue, was the music to which the Canterbury pilgrims performed their journey.

Bagpipe seems to be a translation of the German *Sackpfeife.* By the Italians it is called *Cornamusa;* by the French, *Musette,* not *Chalumeau,* as Dr. Burney states; the latter signifying a single pipe of the simplest kind.

BAHR, the Arabic word for the sea, a lake, or a large river, appears as a component part of many proper names in eastern geography: *Bahr-al-Kolzum,* 'the Sea of Kolzum,' that is, the Arabian Gulf, or Red Sea, especially its north-western extremity (the Sinus Heroopolites); *Bahr Lût,* 'the Lake of Lot,' that is, the Lacus Asphaltites, or Dead Sea, in Syria; *Bahr-al-Abiad,* 'the White River,' and *Bahr-al-Azrak,* 'the Blue River,' that is, the two principal southern branches of the Nile. It has passed into the Portuguese language under the form *Albufeira,* 'a reservoir, a tank, a lagune;' and into Spanish under the two forms of *Albufera* and *Albuhera,* in the same sense. The prefixed *al* in these words is the Arabic definite article; and it is a general remark that the letter *h* of many Arabic words that have been received into the Spanish and Portuguese languages, has been changed into *f.*

BAIL, in civil causes, ordinarily signifies the sureties who become responsible for a defendant arrested by legal process while the cause is yet pending—*mesne* process;—and they are so called, because anciently the defendant was *baillé,* delivered or committed to the custody of his bail, who were bound to produce him at the time appointed for his appearance. By the statute of 23 Hen. VI. c. 9, the sheriff was compelled to admit to bail all persons arrested by him in any personal action, or because of any indictment of trespass, on reasonable sureties being offered for their appearance; and if he refused to take sufficient bail when offered, he was liable to an action by the party arrested. Bail were formerly either *common bail* or *special bail,* a distinction which arose thus: until the commencement of the last century, the defendant was in *all* cases of process against his

* The fourth letter of the name of Eucratides, which on the original coin is an I, was evidently intended for a P, and has probably been damaged a little; compare the P on the coin of Demetrius.

person actually arrested; and it was then discretionary in the court either to discharge him on *common bail* (that is, fictitious sureties, John Doe and Richard Doe) being entered for his appearance, or to detain him till he found real sureties or *special bail*. But this discretion in the court was abolished by the 12 Geo. I. c. 29, which provided that no person should be held to special bail unless the demand amounted to 10*l*., over and above costs, which sum was increased, by the 7 & 8 Geo. IV. c. 71, to 20*l*.; and for less than that sum no debtor could thereafter be arrested and required to give special bail. In all cases where the defendant was not actually arrested, the ancient fiction, stating that he was delivered to bail to John Doe and Richard Doe, continued in the Court of King's Bench to be the only mode of his effectually entering an appearance to the suit till the Act for Uniformity of Process, 2 Will. IV. c. 39, s. 2, which provided, with an exception removed by the Common Law Procedure Act, 1852, sec. 24, that, for the future, the appearance of the defendant should be by entering a memorandum that he either appears in person or by some attorney to the suit instituted by the plaintiff, so that common bail as a step in the cause was thenceforth entirely abolished.

Special Bail.—In considering the subject of special bail, we shall explain: 1, in what cases and in what manner special bail are rendered necessary; 2, who may become special bail; 3, the mode of putting in bail and their justification; 4, the nature and extent of their liability; 5, the mode in which they may be discharged; 6, proceedings on the bail bond and against the sheriff; 7, paying money into court in lieu of special bail; 8, proceedings under the Absconding Debtors Arrest Act, 1851.

1. *In what cases special bail is necessary.*—We have seen that, by the 7 & 8 Geo. IV. c. 71, a defendant could only be arrested and held to special bail (which are convertible terms) where the plaintiff's demand amounted to 20*l*., over and above costs. By a subsequent statute (1 & 2 Vict. c. 110, s. 3) the cases in which a defendant may be held to bail in civil causes are confined to those therein provided. It enacts, that if a plaintiff in any action in any of the superior courts of law at Westminster, in which the defendant is now liable to arrest, shall show by affidavit to the satisfaction of a judge of one of the said courts that such plaintiff has a cause of action against such defendant or defendants to the amount of 20*l*. or upwards, or has sustained damage to that amount, and that there is probable cause for believing that the defendant or any one or more of the defendants is or are about to quit England, unless he or they be forthwith apprehended, such judge may order the defendant or defendants to be held to bail in any sum he may think fit, not exceeding the amount of the debt or damages. The plaintiff may thereupon sue out a writ of capias, and arrest the defendant, who, when so arrested, is to remain in custody till he shall have given a bail bond to the sheriff, or shall have made deposit of the sum endorsed on such writ of capias, together with 10*l*. for the costs. The application for this order is to be made to a judge at chambers, and is, of course, made *ex parte*. It should not be made until after the issue (not service) of the writ of summons, although the affidavit in support of it may be made before. This affidavit must clearly disclose the grounds of the defendant's liability, and show a complete and subsisting cause of action. The amount of the claim should upon no account be overstated. The facts which evidence the intention of the defendant to leave the country must be stated in the affidavit, and it is not sufficient that the deponent merely states his own belief in the existence of such intention. A short and merely temporary absence in the ordinary course of business, as in the case of the captain of a steamer plying between an English and a Continental port, is not a "quitting England" within the meaning of this statute.

A copy of the writ of capias must be delivered by the sheriff to the defendant upon his arrest. Instead of giving bail, he may, under the 43 Geo. III. c. 46, s. 2, recognised by the above enactment, deposit with the sheriff the amount endorsed, with 10*l*. for costs, on receiving which deposit the sheriff is bound to discharge him. If he does not make this deposit under the Statute, he either remains in the sheriff's custody, or is discharged on entering into a bail-bond to the sheriff, with two or more sufficient sureties, the condition of which is, that the defendant shall duly put in special bail to the action within eight days from the execution of the writ: the condition of the bond thus given can only be satisfied by *special bail* being duly put in and perfected, unless money be paid into court under the 7 & 8 Geo. IV. c. 76, s. 2, as will be afterwards explained.

2. *Who may become special bail.*—The general qualification of special bail is that they should be householders or freeholders. A peer of the realm, a member of the House of Commons, a servant in the king's household liable to be called on to attend the king, cannot become bail, all such persons being exempted from the ordinary process of the courts. It is a rule of the courts that no attorney shall become bail, which rule has been extended to their clerks, and was intended to protect attorneys from the importunities of those who employ them; and no person can be bail who is indemnified for his liability by the defendant's attorney. In order to prevent extortion, no sheriff's officer, bailiff, or person concerned in the execution of process can become bail, which rule has been extended to keepers of prisons and turnkeys. Uncertificated bankrupts, and insolvent debtors who have not paid 20*s*. in the pound upon their scheduled debts, are disqualified from becoming bail by their want of sufficient property. For the same reason, persons who have suffered their parents or near relations to receive parochial relief have been rejected. Foreigners cannot become bail merely in respect of property abroad which is beyond the court's jurisdiction; but it seems that British subjects may become bail in respect of property abroad belonging to such British subjects. The special bail, in order to justify, must be worth double the sum indorsed on the writ of *capias*, or if that exceed 1000*l*., then 1000*l*. in addition to it, over and above their just debts.

3. *Of the mode of putting in or recording bail and their justification.*—Special bail may be put in by the defendant himself or his attorney, or by the sheriff or his bail in order to their own indemnity; and they may be put in either before a judge in London or (in vacation) before a commissioner under 1 & 2 Vict. c. 45, s. 4, before a judge of assize in his circuit, or a commissioner in the country. When bail are put in, they are required to make a formal acknowledgment, called a *recognizance of bail*, that they owe to the plaintiff the sum sworn to, and that they undertake to pay the same and all costs, to be levied upon their property, unless the defendant, if defeated in the action, pays the debt or damages, and costs, or renders himself to prison; or, in case he fails to do either, unless they, the bail, pay the costs and money recovered, for him, or surrender him to custody.

Bail is thus put in either absolutely, with the consent of the plaintiff's attorney, which is very unusual in practice, or *de bene esse*, to be perfected, subject to the plaintiff's approval or exception. When put in *de bene esse*, a formal notice in writing of their being put in should be forthwith given to the plaintiff's attorney, accompanied by an affidavit of justification of each of the bail, to the effect that they are freeholders or householders, and are worth the amount necessary for justification, as above explained. Four days' notice of intention simultaneously to put in and justify special bail may also be given where that course is preferred. If notice of justifying the bail was duly given, and accompanied by the affidavits of sufficiency above mentioned, the bail will be considered as justified, unless the plaintiff have given notice of and entered his exception to them at least *one* day before that appointed for their justification. But if the bail were not put in in due time, they must justify whether excepted to or not. If unopposed, the justification is allowed as of course.

The bail may be opposed on their justification by personal examination as to their sufficiency, or by affidavits disclosing such facts as show some irregularity in the proceedings, or that the bail are really incapable of fulfilling their engagement. The corrupt practice of men hiring themselves out as bail is as old as the time of Charles II., when Butler alludes to it, and it continued to a considerable extent until the amendment of the law relating to arrest on *mesne process*. Personating another person, so as to render him liable as bail, was made a capital felony by the statutes 21 Jac. I. c. 26, and 4 & 5 Will. and Mary, c. 4; but by the 11 Geo. IV., and 1 Will. IV. c. 66, s. 11, it was reduced to a felony, punishable with transportation or imprisonment.

4. *Of the extent of the liability of bail.*—We have seen that the bail enter into a recognizance, that if the defendant is convicted, he shall pay the debt or damages, and costs recovered, or render his body to the prison of the court; and therefore if the plaintiff proceed in his action in due time, for the cause of action expressed in the process, and regularly recover judgment, the bail are in general liable to pay the money which he recovers, or to render the defendant to prison. Anciently an absurd practice prevailed, that if a man became bail for another, in however small a sum, he was bail for him in all actions brought by the same plaintiff against the same defendant during the same term, were the sums ever so great: while, on the other hand, if the plaintiff declared in his action against the defendant for a greater sum than was expressed in the process, the bail were wholly discharged. It is now however settled (see Rules of Hilary Term, 1853, r. 109), that whatever sum may be declared for or recovered by the plaintiff in the particular action, the bail remain liable; but they are only together liable to the extent of the sum sworn to by the plaintiff, and the costs of suit, not exceeding in the whole the amount of their recognizance. They are of course further liable to the costs of any proceedings that it may become necessary to take against them to enforce their liability. They are not liable to the costs of proceedings in error against their principal. The liability of the bail on the recognizance attaches, according to its terms, on conviction of the defendant, that is, on final judgment being entered against him; but as the recognizance is in the alternative, they are not immediately fixed with the debt, &c., but have a certain time allowed by the practice of the courts, within which, even after judgment, they may discharge themselves by rendering the defendant's person; the length of which interval is determined by the mode of proceeding by which the plaintiff proceeds against the bail on their recognizance. A writ of *ca. sa.* must have been issued against the defendant, and have been returned before any proceedings can be had against the bail. [Capias.]

5. *The modes in which the bail are discharged.*—The bail are discharged either by performing the recognizance, or by some matters which operate to excuse them from such performance. As to the special circumstances which operate to relieve the bail from their obligation, the general rule is, that wherever by the act of God or by the act of the law, a total impossibility or temporary impracticability to render the defendant has been occasioned, the courts will relieve the bail from the unforeseen consequences of having become bound

for a party whose condition is so changed as to put it out of their power to peform the alternative of their obligation without any default of their own. Thus, if the principal die before the return of the writ of execution (the *capias ad satisfaciendum*) against him, or if before that time he is made a peer of the realm, or become a member of the House of Commons; or if he become bankrupt and obtain his certificate, or be discharged under the Insolvent Act; or if he be sentenced to transportation, and actually on board a convict-ship under such sentence, or be impressed into the Queen's service, or be sent out of the kingdom under an alien act; or if the plaintiff is guilty of some default, as if he do not proceed in due time or in proper manner against the defendant; or if he take a security from the defendant, and thereby give him time without consent of the bail,—in these cases the bail are excused from performance of their obligation, and will be relieved by the courts. In cases where there is not a total impossibility of rendering the bail, but only a temporary impracticability, the courts will not absolutely discharge the bail, but will assist them in other modes; as by issuing a *habeas corpus*, in order to bring up the defendant to be rendered in cases where he is in legal custody for crime, or by enlarging the time for making the render.

6. *Of proceedings on the bail-bond and against the sheriff.*—We have seen, that when the defendant is discharged from arrest, he in most cases enters into a bail-bond with sureties to the sheriff, the condition of which bond is that the defendant do cause special bail to be put in for him to the action within eight days after execution of the *capias*. If special bail are not put in and justified in proper time, according to the rules of practice of the court, this bond becomes forfeited, and the plaintiff then may either proceed against the sheriff by calling upon him to bring in the defendant's body according to the command of the writ; or, if he is satisfied with the bail to the sheriff, he may cause the sheriff to assign over to him the bail-bond, under the statute 4 & 5 Anne, c. 16, s. 20, and may in his own name sue the defendant and his bail on the bond. The plaintiff, by adopting this last course, in general discharges the sheriff from his liability; and therefore it is only resorted to when the sheriff's bail are of undoubted sufficiency. If the plaintiff's proceedings on the bail-bond are *irregular*, they will (like other proceedings) be set aside with costs. But the courts will also stay such proceedings in many cases, even when they are *regular;* the action on the bail-bond being in fact only a subsidiary proceeding for enforcing the general object of bail. In cases where there is really any defence to the original action—any fair question to try—it is obvious that this can only be properly and satisfactorily tried in that action, and not in the collateral action on the bail-bond. Therefore, if the defendant makes application to the court with a proper affidavit of *merits* (that is, a good and lawful defence,) in the original action, the courts will in general stay proceedings on the bail-bond upon terms, so as to give an opportunity for a trial in the original action.

If there is no bail-bond, or if the plaintiff is dissatisfied with the sheriff's bail, he may take proceedings against the sheriff, who is responsible for the due execution of the writ. The plaintiff therefore obtains a rule or order of the court, calling upon him to make a return to the writ (see r. 132, H. T. 1853), which must, by the 20 Geo. II. c. 37, s. 2, be done before six months after the expiration of his office; and the rule must be served on the sheriff or his under-sheriff. This is usually effected by leaving a copy (showing the original) at the office of the sheriff's deputy in London. If there is no return, it is a contempt of court, and an attachment against the sheriff will be granted. To the rule to return the writ the sheriff may make such return as is consistent with the fact, either that the defendant is not found in his bailiwick, or that he has taken him (*cepi corpus*) and has him ready; or that he is sick, or that he has escaped, or has been rescued; or that he has been discharged on making a deposit with the sheriff, under the 43 Geo. III. c. 46, s. 2, &c. &c. If the return is false, the sheriff is liable to an action. If he return *cepi corpus et paratum habeo*, and if special bail are not put in and perfected in due time, the plaintiff may either take an assignment of the bail-bond, if any given, and proceed thereon against the bail, or he may obtain an order of the court requiring the sheriff to bring in the body or person of the defendant. If the plaintiff adopt the latter course, the sheriff must either bring the defendant (*constructively*, by showing him to be in his safe custody,) into court, or he must put in and perfect bail within the time allowed by the rule. If he fail in this it is a contempt of court, for which an attachment will issue on an affidavit that the rule has been duly served, and that no bail is put in. As these proceedings against the sheriff are (like the proceedings on the bail-bond) regarded by the courts as only intended to enforce the attainment of sufficient bail, the courts will also in this case extend their indulgence to the sheriff, and stay the proceedings against him, and let in a trial on the merits for the benefit of the sheriff, or the bail, or the defendant, on good bail being put in and perfected.

The rules on the subject of bail, which were formerly very complicated, and different in each separate court, have been of late much simplified by rules of court, and by the statute above cited, for uniformity of process, which was introduced by the late Lord Tenterden.

7. *Paying money into court in lieu of special bail.*—In cases where the defendant has, in pursuance of the 43 Geo. III. c. 46, s. 2, in lieu of bail to the sheriff, deposited in his hands the sum indorsed on the writ, and 10*l*. for costs, to answer the costs up to the eighth day inclusive after the arrest, and the sheriff has paid these into court, as he is bound to do, the defendant, instead of putting in and perfecting special bail, may, by virtue of the 7 & 8 Geo. IV. c. 71, s. 2, allow such sums, together with the additional sum of 10*l*. to be by him paid into court as a further security for costs, to remain in court to abide the event of the suit. In other cases, where the defendant has not made such deposit with the sheriff, the defendant, instead of putting in and perfecting special bail, may deposit and pay into court the sum indorsed on the writ, and 20*l*. as a security for the costs of the action, there to remain to abide the event of the suit. In either case, defendant should enter an appearance to the writ of summons; and if judgment be given for the plaintiff, he will be entitled, by order of the court upon motion, to receive the money so remaining in, or so deposited or paid into court, or so much thereof as will be sufficient to satisfy the sum recovered by the judgment and the costs of the application. And if judgment be given for the defendant, or the plaintiff discontinue or be otherwise barred, or if the sum deposited and paid into court be more than sufficient to satisfy the plaintiff, the money so deposited or paid into court, or so much thereof as shall remain, will, by order of the court upon motion, be repaid to the defendant.

8. *Proceedings under the Absconding Debtors' Arrest Act*, 1851.—Further legislative provision has been made by 'The Absconding Debtors' Arrest Act, 1851,' which empowers country commissioners of bankruptcy, and judges of county courts beyond the metropolitan district, to issue, upon similar application and similar affidavit to those above considered, a warrant for the absconding debtor's arrest, to the messenger of the commissioners of bankruptcy, or to the high bailiff of the county court, indorsed in the same manner as a writ of *capias*. This warrant may be executed at any time within seven days from its date inclusive; the officer executing it must detain the debtor until he has paid the debt and costs indorsed on the warrant, or given bail according to the practice of the superior courts, or is otherwise lawfully discharged. A copy of the warrant must be served upon the debtor when arrested. The warrant may be executed in any part of England, and is to be transmitted, if necessary, from the bailiff of the county court whence issued to the bailiff of any other county court within the district of which the debtor is supposed to be, and such latter bailiff may lawfully execute it, as though it had been directed to him by the judge of the county court out of which it issued. But as this warrant is only auxiliary to the process under the 1 & 2 Vict. c. 110, s. 3, it becomes void and of no effect as a protection to the creditor, unless a *capias*, and, in cases where no action was pending in the superior courts, a writ of summons therein, be forthwith issued and served within seven days from the day of the date of the warrant inclusive. Upon such service of the *capias*, the debtor is deemed to have been arrested by virtue of the *capias*, and all proceedings must be had upon it as if it had been issued prior to the issuing of that warrant, and according to the ordinary practice. If the debtor, upon his arrest under the warrant, pays the debt and costs, and is accordingly released from custody, the *capias* must be issued, but need not, of course, be served. The debtor, when arrested, may at once pay the debt and costs indorsed on the warrant to the officer duly arresting him, or enter into a bail-bond to him with two sufficient sureties for the amount indorsed, conditioned to put in special bail as required by the warrant, or to make deposit of the sum so indorsed, together with 10*l*. for costs, and thereupon he is entitled to be discharged from custody. Any person for whose arrest a warrant has been granted may, either before or after arrest, and before the writ of *capias* has been issued, apply to any commissioner of bankruptcy or county court judge, or to any judge of the superior courts, or to the court mentioned in the affidavit of debt or warrant for the arrest, for a summons or rule calling upon the creditor who has the warrant to show cause why it should not be set aside (if the application is made before arrest), or why the debtor should not be discharged out of custody (if the application is made after arrest); and the commissioner or judge may make absolute or discharge the summons or rule, and direct the costs of the application to be paid by either party, or make such other order therein as he thinks fit; but such order may be discharged or varied by the court, on application made by either party dissatisfied with it. (See Archbold's 'Practice,' 10th edit., by Prentice, vol. i. pt. 2; and Pollock's 'County Court Practice,' 3rd edit. pt. 1, cap. 26.)

Bail in error.—These are sureties required to be given by a defendant at law, who sues out a writ of error to reverse a judgment which has passed against him, and who desires to stay execution in the meantime. The condition of the recognizance into which they enter is, that the party suing out the writ of error shall prosecute it with effect, and if the judgment be affirmed, shall satisfy the debt and costs recovered, together with all such costs and damages as are awarded by reason of the delay of execution occasioned by the writ of error, or else that the bail shall do it for him. By the common law, no bail in error was required, and a defendant might therefore delay a plaintiff of his execution without giving any security to prosecute his writ of error, or to pay the debt and costs if the writ failed. This inconvenience was only partially remedied by the statute 3 Jac. I. c. 8, which required bail in error only in certain particular actions, and by the 13 Car. II. stat. ii, c. 2, and the 16 & 17 Car. II. c. 8, which rendered it necessary only where the judgment was after verdict, and not in cases where the defendant suffered judgment by default. And accordingly it became the common practice of defendants sued upon bills of exchange and other simple contracts, and having no real defence, to delay the plaintiff by suffering judgment by default, and then by bringing a writ of error, in which case they were under no obligation to find bail. These delays were suppressed by an Act, 6 Geo. IV. c. 96, s. 1, introduced by the late Sir Robert Peel, which required bail on every writ of error after judgment for the plaintiff, whether by default or after verdict, unless otherwise ordered by the court or one of its judges. The practice is now regulated by the 'Common Law Procedure Act, 1852,' the provisions of which consolidate the previous law, and extend to cases of error *in fact*, to which the above cited statute of Geo. IV. did not apply. The bail must be put in within four days after lodging the memorandum alleging error, or after the signing final judgment, otherwise the plaintiff in the original action may proceed to take out execution. The recognizance is taken in double the sum recovered by the judgment, except in the case of a penalty, where it is limited to double the sum really due and double the costs. The bail must justify, if required, and may be opposed by the plaintiff; but as the engagement is not alternative, like that of the bail in the original action, but absolute to pay the sum recovered and costs, bail in error cannot discharge themselves by surrendering their principal; nor are they entitled to relief if their principal becomes bankrupt. By the 'Common Law Procedure Act, 1854,' an appeal somewhat in the nature of a writ of error is given in certain cases, upon the refusal, or making absolute, or discharging, rules for new trials, or for nonsuit, or to enter verdicts; and upon such appeals it is provided, sec. 38, that notice of appeal shall be a stay of execution, provided bail to pay the sum recovered and costs, *or to pay costs where the appellant was plaintiff below*, be given in like manner and to the same amount as bail in error, within eight days after the decision complained of, or before execution delivered to the sheriff. (See Archbold's 'Practice,' 10th edit., by Prentice; vol. i. pt. 1. cap. 26, and vol. ii. pt. 5, cap. 28.)

Bail in Criminal Cases.—These are the sureties given to the crown by a party accused of a crime, who is allowed by a court or magistrate to be at liberty till trial, on giving security for his due appearance. By the common law, all accused persons, even though charged with heinous felonies, were allowed the privilege of bail, till the crime of murder, and afterwards treason, and other felonies, were excepted by statute. Further regulations were introduced on the subject by statutes of Henry VI., and of Philip and Mary, which contained many nice distinctions as to the offences which were bailable, and those which were not so. The provisions of these statutes respecting bail, were extended by the 7th of Geo. IV., c. 64, s. 1, introduced by the late Sir Robert Peel. A subsequent statute, 11 & 12 Vict. c. 42, s. 23, now regulates the law of bail in all cases of felonies, and also of those misdemeanors which are by statute excepted from the common law right of bail. This common law right of bail in all other misdemeanors is recognized and enforced by the same enactment. It enacts that any person charged before a justice with any felony (not being treason), or with any assault with intent to commit felony, obtaining or attempting to obtain property by false pretences, receiving property stolen or obtained by false pretences, perjury or subornation of perjury, concealing the birth of a child by secret burying or otherwise, wilful and indecent exposure of the person, riot, assault in pursuance of a conspiracy to raise wages, assault upon a police officer in the execution of his duty, or upon any person acting in his aid, neglect or breach of duty as a peace officer, or any misdemeanor for prosecution of which the costs may be allowed, may be bailed *at the discretion* of the justice or justices. By section 21, provision is made for bailing persons remanded for further examination; and see hereon in cases of summary jurisdiction the 18 & 19 Vict. c. 126, ss. 5 & 6; and the 20 & 21 Vict. c. 43, s. 3. In cases of treason, the justices have, as above stated, no power of taking bail, but such power is reserved to a Secretary of State, to the court of Queen's Bench, or in vacation to a judge thereof.

The recognizance of bail is conditioned for appearance and surrender of the person charged, at the time and place of trial, and for his then and there pleading and taking his trial, and not departing without leave. This recognizance may in certain cases be removed to the Central Criminal Court, under the 19 & 20 Vict. c. 16, s. 10, and the person charged may, after appearance at such court, be again bailed or committed to Newgate, s. 22. Bail may at any time seize and surrender their principal, and thus discharge themselves.

The above-mentioned Acts apply only to the taking of bail by justices of the peace, and do not in any way affect the authority of the superior courts of law to admit prisoners to bail. The courts of Common Pleas and Exchequer, and the Court of Chancery, may, by the common law, award a *habeas corpus* to bring up any person committed for a crime under the degree of felony or treason, and may discharge him, if it appear that the commitment was illegal, or bail him if it appear doubtful. The authority of the chancery is said, indeed, to extend to cases of felony; that of the other two courts is confined to misdemeanors. The Court of Queen's Bench has a more extensive authority; that court, or any one of its judges in time of vacation, may bail a party committed for any crime whatever, even for treason or murder; and they will in general exercise this authority in cases not capital, and also in capital cases, where the circumstances raise a presumption of the party's innocence. But neither the Court of Queen's Bench nor any other court can bail prisoners in execution, or suffering imprisonment under the sentence of a competent court for crime, or for a contempt of its authority, unless indeed it is plainly made to appear to that court that they are not guilty of the offence, or unless a prisoner is in danger of losing his life from the effects of continued confinement. And it seems now to be considered as settled that the Court of Queen's Bench has no authority to admit to bail a person committed by either House of Parliament so long as the Parliament is sitting; though, when the session is at an end, it seems admitted that it possesses such power. Metropolitan police magistrates have under the 2 & 3 Vict. c. 71, s. 36, special powers of bailing persons charged before them, even upon their sole recognizance, without surety. Justices of the peace have also special powers under the Juvenile Offenders Act, 10 & 11 Vict. c. 82, s. 15, of bailing either upon remand or commitment for trial, or upon suffering to go at large. Under the 11 & 12 Vict. c. 78, s. 1, the Act establishing the court for the consideration of Crown cases reserved, convicted prisoners upon whom judgment has been postponed, or the execution respited, may be admitted to bail by the court before which they were tried, and this power would seem to extend even to cases of treason. Persons convicted of misdemeanor, and having obtained a writ of error to reverse the judgment, may obtain an interim stay of execution and discharge from custody, provided they enter into a recognizance with two sufficient sureties to prosecute the writ with effect, to appear in court to receive judgment, and to surrender if the judgment be affirmed. See 8 & 9 Vict. c. 68, ss. 1, 2; 9 & 10 Vict. c. 24, s. 4., and 16 & 17 Vict. c. 32, ss. 1, 2. The bail taken, should be such as in the opinion of the justice admitting to bail, will be sufficient to secure the appearance and surrender of the person accused at the time and place of trial. Care must however be taken, at least in all cases bailable as of right, not to require such excessive bail as in effect to amount to a denial of bail, which is one of the grievances complained of by the Bill of Rights (1 Will. & Mary, st. II., c. 2), and prohibited by that Act.

By the 10th Geo. IV. c. 44, s. 9 (the Metropolis Police Act), it is lawful for any constable in London attending at any watchhouse in the night time, to take bail from persons charged with petty misdemeanors, without warrant of a justice, and such recognisances shall be of equal obligation as if taken by a justice of the peace.

(See Blackstone's *Comm.*, by Dr. Kerr, vol. iv. p. 349, et seq.; Bacon's *Abridgment*, tit. 'Bail in Criminal Cases,' 7th edit.; and Archbold's 'Criminal Practice,' 14th ed., by Welsby.)

BAIL. In Scotland, this term properly is confined to criminal law. In the civil courts the proper term is *caution.* Anciently, pledges of prosecution and appearance were demanded from litigants no less universally than in England; the judicial writs in both countries being then essentially the same. The writs which originate proceedings in the Court of Session however do not now make mention of pledges; and, accordingly, bail is now known in the Scottish civil courts only in exceptional cases. Two kinds were formerly in use,—caution *judicio sisti*, and caution *judicatum solvi*; phrases derived from the civil law through the medium of the old French courts, and answering to the forthcoming borgh, and the surety as law will, of the ancient common law of Scotland. Both kinds long continued in use in maritime causes, but by 13 & 14 Vict. c. 36, s. 24, they are abolished in such causes in the Court of Session; and by 1 & 2 Vict. c. 86, s. 22, caution *judicatum solvi* cannot be demanded in such causes in the Sheriff Courts, unless by leave of the judge on cause shown.

The cases in which bail may still be received in civil actions in Scotland are those in which the debtor may be arrested on *foreign* warrant or *flight* warrant. Foreign warrants are of two kinds, usually called *burgh* warrants and *border* warrants. Of all these, the burgh warrant appears the most ancient, and from it the others are perhaps derived. It seems also to have a common origin with the *foreign attachment* of London, Bristol, and other towns of England.

The *burgh warrant* is a burghal or civic proceeding directed against non-resident debtors. It appears as early as the reign of King David II., by cap. 36 of whose laws it was enacted, that if any stranger take up goods or necessaries within burgh, and offer to go away leaving the same unpaid, he shall be attached and detained by public warrant. At length, after various determinations of the courts on the subject, which it is not necessary here to detail, the Act 1672, c. 8, was passed, by which the custom is now regulated. The following particulars may thence be gathered:—The privilege is limited to royal burghs, and to book debts for man's meat, horse meat, and other merchandise due by a stranger to an inhabitant burgess, the plaintiff being the merchant, innkeeper, or stabler from whom the same was gotten, and to whom it was originally addebted, and having no bond from the stranger nor any other security except his own compt-book; and the remedy is arrest and imprisonment of the stranger, by warrant of the magistrates, till he find caution *judicio sisti* in any process to be brought for payment of the debt within six months. *Border warrants* are granted, on application to any judge ordinary, on the borders between England and Scotland, against debtors whose domicile is on the opposite side, for arresting them till they find like caution *judicio sisti.* To obtain a *flight* warrant, *fugæ* warrant, or warrant against a debtor as *in meditatione fugæ*, a petition is presented to any judge ordinary by the creditor, stating his debt, and his information and belief that the debtor is about to flee the kingdom without paying the same, and praying warrant to bring him before the court for examination. With this petition the creditor produces his vouchers of debt. He must also make an affidavit of his debt, and of his belief that the debtor means to abscond, and of the facts on which such belief is founded. If the circumstances are sufficient, the magistrate or judge then issues his warrant to bring the debtor before him for examination. If, after due inquiry, it appear that the debtor is about to flee the kingdom to defraud his creditor, warrant is granted in terms of the application, to seize and imprison him till he find caution *judicio sisti*.

The Scotch law of bail in cases of crime is shut up within a narrow compass, it being almost altogether contained in the Acts 1701, c. 6, and 39 Geo. III. c. 49. By the former, all capital crimes are made bailable. It may be remarked, that although capital sentence is not, nor, under the forms of Scottish law as now in practice, can be pronounced by a judge in the case of any crimes except murder and high treason, yet many of the more heinous offences, as robbery, rape, aggravated theft, arson, &c., are still by statute capital, and are consequently not bailable of right. (Parl. Papers, Sess. 1855, No. 419.) But the chief criminal court, or the lord advocate, as public prosecutor, may admit to bail even in capital cases. (Alison's Crim. Prac., 163, 166.)

In all except capital cases the accused is entitled to be admitted to bail on application to the judge committing or other judge having jurisdiction. By 39 Geo. III. c. 49, the bail is not to exceed 1200*l.* for a nobleman, 600*l.* for a landed gentleman, 300*l.* for any other gentleman, burgess, or householder, and 60*l.* for an inferior person.

BAILEY, or BAILLIE. [BALLIUM.]

BAILIFF signifies a keeper or superintendent, and is derived by us from the French word *bailli*, which appears to come from *ballivus*, and that from *bagalus*, the Latin word signifying generally a governor, tutor, or superintendent, and also designating an officer at Constantinople who had the education and care of the Greek emperor's sons. (Du Cange, 'Glossary.') All the various officers who are called by this name, though differing as to the nature of their employments, seem to have some kind of keeping or superintendence intrusted to them by their superior. The sheriff is called the queen's bailiff, and his county is his bailiwick. The keeper of Dover Castle is called the bailiff; and the chief magistrates of many ancient corporations in England have this name. But the chief functionaries to whom the name is applied, are the bailiffs of sheriffs, the bailiffs of liberties or franchises, and the bailiffs of lords of manors.

1. *Bailiffs of sheriffs* were anciently appointed in every hundred, to execute all process directed to the sheriff, to collect the king's fines and fee-farm rents, and to attend the justices of assize and gaol delivery: they are called in the old books *bailiffs errant*. There is now a certain number of bailiffs appointed by the sheriff in his county or bailiwick, who, from their entering into a bond to the sheriff in a considerable penalty for their due and proper execution of all process which the sheriff intrusts them to execute, "are called *bound* bailiffs, which (says Blackstone) the common people have corrupted into a much more homely appellation." These are called *common* bailiffs; but the sheriff may, and often does, at the request of the suitor or otherwise, intrust the execution of process to a person named merely *pro hâc vice*, who is called a *special* bailiff, and for whose acts the sheriff is not liable to the party obtaining him employment. The bailiff derives his authority from a warrant under the hand and seal of the sheriff; and he cannot lawfully arrest a party till he receives such warrant. It is a contempt of the court from which process issues, to hinder the bailiff in executing it; and when a party is taken by the bailiff, the law considers him in the custody of the sheriff. An arrest may be made by the bailiff's follower; but the bailiff must in such case be at hand and acting in the arrest. If a bailiff misdemean himself grossly in the execution of process, as if he use unnecessary violence or force, or extort money from prisoners, or embezzle money levied, he will be punished by attachment from the court from whence the process issues.

2. *The bailiff of a franchise or liberty* is one who has the same authority granted to him by the lord of a liberty as the sheriff's bailiff anciently had by the sheriff. These liberties are exclusive jurisdictions, which still exist in some parts of the kingdom (as the honour of Pontefract in Yorkshire, the liberty of Gower in Gloucestershire, and adjoining counties,) in which the king's writ could not formerly be executed by the sheriff, but only by the lord of the franchise or his bailiff. These districts proving inconvenient, the Statute of Westminster the Second, c. 29. provided, that if the bailiff, when commanded to execute a writ within the franchise, gave no answer, a writ, with a clause of *non omittas*, should issue, authorising and commanding the sheriff to enter the franchise and execute the writ; and it has long been the practice in every case to insert this clause in the writ, in the first instance, which enables the sheriff at once to execute it in the franchise.

3. *Bailiffs of manors* are stewards or agents appointed by the lord (generally by an authority under seal) to superintend the manor; collect fines and quit-rents; inspect the buildings; order repairs; cut down trees; impound cattle trespassing; take an account of wastes, spoils, and misdemeanors in the woods and demesne lands; and do other acts for the lord's interest. Such a bailiff can bind the lord by acts which are for his benefit, but not by such as are to his prejudice, without the lord's special authority.

(Bacon's *Abridgement*, tit. Bailiff.)

BAILIWICK, from the French *bailli*, and the Saxon ƿic (*vicus*), the street, dwelling-place, or district of the bailiff, signifies either a county which is the bailiwick of the sheriff, as bailiff of the king, and within which his jurisdiction and his authority to execute process extend; or it signifies the particular liberty or franchise of some lord who has an exclusive authority within its limits to act as the sheriff does within the county. [BAILIFF; SHERIFF; BAIL.]

BAILLIAGE, a French term equivalent with bailiwick, a district or portion of territory under the jurisdiction of an officer called a bailiff. This term was more especially appropriated to certain sub-governments of Switzerland, which at the time Coxe wrote his travels were of two sorts: the one consisting of certain districts into which all the aristocratical cantons were divided, and over which a particular officer called a bailiff was appointed by the government, to which he was accountable for his administration; the other composed of territories which did not belong to the cantons, but were subject to two or more of them, who by turns appointed a bailiff. The officer of this last sort of bailliage, when not restrained by the peculiar privileges of certain districts, had the care of the police, and under limitation the jurisdiction in civil and criminal causes. He also enjoyed a stated revenue, arising in different places from various duties and taxes. In case of exaction or mal-administration an appeal lay to the cantons to which the particular bailliage belonged. (Coxe's 'Trav. in Switz.,' 4to, Lond., 1774.) The latter bailliages anciently formed part of the Milanese. They have been formed since into the canton of Ticino. [TICINO, in GEOG. DIV.]

BAILMENT, in law, is a term derived from the French word *bailler*, to deliver, and may be defined to be "a delivery of goods for a particular purpose, upon a contract, express or implied, that the purpose shall be carried into effect, and that, when that is done, the goods shall be restored, by the bailee or person to whom they are delivered, to the owner or bailor, or, according to his directions." The degree of responsibility which attaches to a person who receives goods or other property belonging to another, depends entirely upon the circumstances of the delivery; and as those circumstances are infinitely varied, the subject is one of considerable nicety; while its connection with the transactions of commerce and the daily occurrences of life renders it of great practical importance.

The whole English law of bailment rests upon the Roman law, from which it derives not only its doctrines but its technical terms. In this article it will be sufficient to enumerate the general rules which have been established by the law of England respecting bailment; under some one of which the cases which ordinarily occur in practice are in general comprehended. The most convenient and accurate method of classifying the different species of bailments is that suggested by Sir William Jones, in his 'Essay on the Law of Bailments;' we shall follow his arrangement of the subject, using the Latin names which are common to the English and Roman law.

I. *Depŏsitum* is a mere delivery or simple deposit of goods to be kept by the bailee for the bailor without remuneration. In cases of this kind, the main obligation imposed upon the bailee is faithfully to return the goods upon demand; and he is not liable for the loss or injury of the property deposited with him, unless it has been occasioned by wilful abuse, or gross negligence. In the Roman law, gross negligence was denominated *magna*, or *lata culpa*, and was held to be presumptive evidence of fraud, when applied to cases of trust. And the same principle is adopted by Lord Holt in the case of *Coggs* v. *Bernard* (2 Lord Raymond, 913); but, according to the more recent authorities on this subject, gross negligence, although it may be evidence of *mala fides*, is not identical with it. (*Goodman* v. *Harvey*, 4 A. & E. 870, 876.) The measure of diligence required from the bailee in cases of mere deposit, or, as they are sometimes called, general bailments, is that which a prudent man would use in his own affairs. If, for instance, his house is on fire and he saves his own goods, leaving those deposited to be burned, though he had time and power to save both, he will be bound to restore the value to the owner; if, on the other hand, he is only able to save one of them, he is at liberty to prefer his own, unless the deposited property be obviously of much greater value; in which case it is said that the bailee ought to save it, and that he may then claim indemnification from the depositor for his own loss. But there is no rule in our law to the effect, that if a gratuitous bailee keep the goods as he keeps his own, he is not answerable for loss or damage, however careless or negligent he may be. There are, indeed, some expressions in the judgment of Lord Holt, in the case of *Coggs* v. *Bernard*, from which it may be collected that this was his opinion. But the modern cases show that such a bailee may be guilty of gross negligence, although he may have kept the goods entrusted to him with as much care as he kept his own; and that if he be guilty of gross negligence, the negligent keeping of his own goods will be no defence. (*Dooman* v. *Jenkins*, 2 A. & E. 256.)

II. *Mandatum*, or commission, is a delivery of goods for the purpose of having them carried from one place to another, or of having some act performed upon them, for which service the bailee is to receive no reward or payment, and from which the depositor alone is to derive benefit. The distinction between this kind of bailment and a mere deposit, is that the former implies some act to be done by the bailee, whereas the latter simply relates to custody. Hence arises a difference in the nature of the duty imposed, which is not merely to return the property to the owner, but to execute the commission which, by the acceptance of the goods for that purpose, the bailee has engaged to perform. There is, however, no real difference in the two cases as to the degree of liability incurred by the bailee; for his acceptance of the commission implies an undertaking to do as much towards the execution of it, as he would do if he were performing his own work; and accordingly, if he be guilty of gross negligence or breach of faith, he may be charged with any loss occasioned thereby.

III. *Commodatum*, is a loan of goods to be used by the person to whom they are lent or delivered, without pay. In this case, as the bailee alone derives a benefit from the transaction, a proportionate increase of obligation and responsibility is cast upon him. Where a chair, a book, a carriage, or any other article is lent for the accommodation of the borrower, he is bound to re-deliver it specifically in as good condition as it was in when delivered to him, subject only to the deterioration produced by the ordinary and reasonable use of it for the purposes of the loan: and he is also bound to indemnify the lender against any loss or damage which might have been avoided by very great care and vigilance. A borrower, therefore, is answerable not only for slight, but for the slightest neglect; he is to use not merely ordinary, but the greatest possible care; and it is not sufficient to exonerate him from responsibility for the loss or injury of the article borrowed, that he has taken as much care of it as of his own property; it is his duty to apply the utmost care of a careful and vigilant man. Thus, if I place a borrowed horse in a ruinous stable, and a violent tempest blows down the stable and kills the horse, I must bear the loss; because a very careful man would have repaired the stable, or would not have put the horse into it; while, on the other hand, if the stable had been in good repair, and had fallen from the violence of the tempest only, I should not have been liable. Even if the goods be stolen from a borrower, he must indemnify the owner, unless he has observed the greatest care, and used every precaution to prevent the occurrence. Thus, if I lock up a borrowed horse in my stable, and robbers break the door and steal him, I am not chargeable; but if I or my servants neglect to lock the stable-door, and thus give an opportuuity to the robbers, I shall be liable, because my negligence has contributed to the loss. This instance will also serve to illustrate a distinction between a loss by robbery and a loss by theft, which is fully adopted into our law from the Roman law. If I neglect to lock the stable-door, in consequence of which the horse is stolen, this is a case of theft, which would not have happened but for my neglect; whereas if robbers break the door and take the horse, this is a case of robbery or overpowering violence, which no care of mine could prevent. "Adversus *latrones*," says the civil law, "parùm prodest custodia; adversus *furem* potest, si quis advigilet." There may, however, be a case in which a borrower will be liable, though the borrowed article be taken from him by superior force. Thus, if I borrow a horse for a journey, and instead of taking the common road, I ride across a country notoriously infested by robbers, in consequence of which I am assailed and the horse is killed or taken from me: in such a case, I shall be chargeable, because the loss was occasioned by my imprudence in quitting the main road. The borrower of an article is also bound to use it for no longer time and for no other purpose than those for which it was lent. Thus, if I borrow a horse for a week to ride to Bath, and instead of using him for that time and purpose, I ride him to Oxford, and keep him a month, I am liable to indemnify the lender for any accident which may befal the horse in the journey to Oxford, or after the expiration of a week. So also, if I lend a borrowed horse to another person, in consequence of which the horse is injured, I must indemnify the owner.

IV. *Vadium*, is a delivery of goods in pledge or pawn as security for some debt or engagement. In this case a benefit is derived by each party to the transaction: by the pawnee, by his having a profit on the loan and also a security for it; and by the pawnor, by his having the advantage of goods or money on credit. The duty, therefore, of the bailee in this case is to take *ordinary* care of the property while in his custody,—such care, namely, as a careful man bestows upon his own property. He is not bound to use the most exact diligence, as in the case of a borrower for use; but he is responsible for less than gross neglect. As the presumption is, that a bailee does not use ordinary diligence who suffers the goods deposited with him to be taken away by *stealth*, it follows that if they are simply *stolen* from him, he is liable to account for them to the pawnor, unless he can show by the circumstances of the transaction, that he was in no default. But the distinction above mentioned between a theft and a robbery exists in this case also; and, therefore, a pawnee is not liable if he be forcibly robbed without any misconduct or neglect on his part. So in case of his house being accidentally burnt, the pawnee is not liable to restore to the owner the value of goods pawned, if he has used ordinary care to prevent the occurrence of such an accident. The pawnee is not, in general, at liberty to use the thing pawned; although if such use were necessary for its preservation, or otherwise beneficial to it; or if, where the pawn is an animal, it were used as a recompense for the cost of its keep, the law would perhaps imply the consent of the pawnor, to the use of the article pledged. Such use, however, is always at the peril of the pawnee who must indemnify the owner in all cases, even of robbery by violence, if the goods pawned are lost by him while he is wearing or otherwise using them.

V. *Locatum*.—This species of bailment, which is of the most extensive importance in the common affairs of life, is where an article is delivered to the bailee, on the terms that a payment or remuneration shall be made, either by the bailee for the use of it, or by the bailor for work and services to be performed by the bailee upon the article delivered to him. For more clearly understanding the relative rights and duties of the parties to this kind of bailment, it may be conveniently divided into two parts: 1. A bailment of goods to be used by the hirer for a compensation to be paid by him to the owner, which contract is called *locatio rei;* and, 2. A delivery of goods for the purpose of having work done upon them, or of being safely kept for the owner; and in each case for a reward or payment to be given or made to the bailee by the owner. This latter contract is called *locatio operis.*

A third division has been made by some authors, namely, *locatio mercium vehendarum*, where goods are bailed for the purpose of being carried from one place to another, for reward to the carrier. This seems, however, to be merely an instance of the *locatio operis.*

With regard to the first of these divisions, the modern and approved doctrine is, that the hirer of goods for a payment to the owner is bound to keep them with ordinary care, that is, with that degree of care which a careful man uses in keeping his own goods. If, therefore, I hire a horse, I am bound to treat it in all respects with the same care and moderation with which a man of common sense and prudence would treat his own horse; if I place it in a stable and leave the door open, so that it is stolen through my negligence, I must indemnify the owner; but I am not answerable if it be violently taken from me by robbers; unless, by riding at unseasonable hours, or travelling by unusual roads, I have imprudently placed myself in the way of danger. So, also, if I hire a house, lodging, or carriage, I must take the same care of them, and of the conduct of my servants and family respecting them, as a prudent and discreet man would take of his own property.

A bailee of goods for hire, even for a time certain, by *selling* the goods, determines the bailment; and the bailor may sue the purchaser as for a conversion thereof, although the purchase was *bonâ fide.* And so if, during the bailment, the goods are taken in execution for a debt of the bailee, this puts an end to the bailment, and the bailor may sue as for a conversion of the goods.

The second kind of bailment comprised under this general head, namely, *locatio operis*, is of very general occurrence. Not only manufacturers and artizans, who have materials delivered to them to work up, but innkeepers, carriers, factors, wharfingers, and warehousemen fall under this general head. But as innkeepers, factors, and carriers are exposed to a greater degree of responsibility by the law of England than that of mere bailees for hire, by means of acts of parliament and ancient customs, we refer, for the details of their liabilities, to CARRIER, FACTOR, and INN. Generally speaking, all bailees of this description, who in fact let their skill and attention to hire, are bound to take *ordinary* care of the things respectively bailed to them. With respect to manufacturers or artizans, they are not only bound to keep with ordinary care the goods deposited with them to be worked upon, but they must also apply a degree of skill equal to the performance of the particular kind of work committed to them. This obligation is founded upon the presumption, that every man possesses the ordinary skill required for the art or business he professes. The doctrine of the civil law is, that every person professing an art or handicraft *spondet peritiam artis;* and the consequence of this doctrine is that *imperitia culpæ numeratur.* If, therefore, I deliver cloth to a tailor with directions to make it into a coat, and if, for want of having the ordinary skill of his trade, he cuts it so as to spoil the cloth, he must indemnify me for the loss. With respect to agisters of cattle, wharfingers, and warehousmen, it may be stated generally that they are all responsible for want of good faith, and of reasonable and ordinary care and diligence, and not to any greater extent unless under peculiar circumstances.

(Upon the whole of this subject, see Sir William Jones's *Essay on the Law of Bailments;* Bacon's *Abridgment*, title 'Bailment'; Pothier's *Traités des Contracts, &c.;* and Kent's *Commentaries on American Law;* in which latter work the subject of bailment is treated in a most perspicuous manner.)

BAIRAM is the designation of the only two festivals annually celebrated by the Turks and other Mohammedan nations. The word is Turkish, and means a feast day or holiday. The first is also called *Id-al-Fitr*, that is, "the festival of the interruption," alluding to the breaking of the universal fast which is rigorously observed during the month Ramadan or Ramazan. This is, according to Sale, properly the lesser Bairam, but from having been celebrated more generally, and for a longer period than the other, it is now almost universally distinguished as the Grand Bairam. It commences from the moment when the new moon of the month Shawall becomes visible, the appearance of which, as marking the termination of four weeks of abstinence and restraint, is looked for and watched with great eagerness. At Constantinople it is announced by the discharge of guns at the seraglio upon the sea-shore, and by the sounding of drums and trumpets in all public places of the city. This festival ought, properly, to last but one day; but the rejoicings are generally continued for two days more. In other parts of Turkey, and in Persia, it is prolonged by the lower orders at least for five or six days, or even longer. The second festival, denominated *Id-al-Azhá*, or *Kurbán Bairám*, that is, "the festival of the sacrifices," is instituted in commemoration of Abraham offering his son Isaac, and is celebrated seventy days after the former, on the 10th of Dhu'lhajja, the day appointed for slaying the victims by the pilgrims at Mecca. It lasts three days, the first being the most solemn day of the pilgrimage, but as the ceremonies are only imitations of what takes place at Mecca, it is observed with much less strictness, and has, therefore, obtained the name of the Lesser Bairam. At each of these festivals but one *khutba* is read, that is, divine service is only once publicly performed, on the first day, about an hour after sunrise; and in the Turkish empire even this solitary act of public worship is now no longer announced by the muezzins, or public criers, from the tops of the minarets or turrets of the mosques. At Constantinople the two Bairáms are celebrated with much pomp. The sultan on this occasion receives the homage of the different orders of the empire, and proceeds in state, followed by all the higher officers, to the mosque. As the Mohammedans have a lunar year of 354 days, the two festivals run, once every thirty-three years, through all the seasons.

(Sale's *Koran*, Preliminary Discourse, s. vii.)

BAKING. [BREAD; ENAMELLING; GLASS-MANUFACTURE; POTTERY.]

BALANCE, a corruption, probably, of the middle Latin word *Valentia*, used (see Ducange) to denote price or value; whence came *valance*, mentioned by the same author, who considers the word *Balanx*, or *Bilanx*, to be a re-construction from the common idiom. The word *ballancia* is found in the 13th century. From meaning the worth or value, it came to signify any instrument used for ascertaining it, but particularly when weight was the quality referred to. Hence came the general meaning of the term, in which it stands for any state of things under which opposing circumstances just destroy the effects of each other; as when we speak of a balance of power, of good and evil, &c. Hence also the commercial meaning, in which the balance is not the state just mentioned, but the sum of money which must be added to one or the other side of an account, in order that the debts and credits may be *balanced*, or of equal amount. As an instrument of common use, the term *Scales* is more frequently applied. In philosophical apparatus, the word is applied to any machine by which an effect is measured, at the pleasure of the inventor, for there is no other rule. For the hydrostatical balance, see GRAVITY, SPECIFIC; for the torsion balance, see TORSION, &c. [STEEL-YARD, LEVER, COIN WEIGHING-MACHINE, SPRING-BALANCE.]

The instrument most commonly known by the term balance is a superior sort of scales, executed with all the precision necessary for the nicest operations of physics, and particularly of chemistry. We shall therefore confine ourselves to a statement of the circumstances which are necessary to a good performance of the philosophical balance.

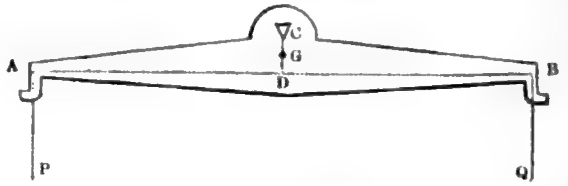
A simple straight lever, balanced by weights resting immediately upon it, so that the centre of gravity fall on the fulcrum, is at rest in every position: for no motion will change the position of the centre of gravity. The same may be said when some of the weights hang by strings; firstly on the mechanical principle that any force may act at any point of its direction, and secondly, by a geometrical theorem, which points out that when weights either hang by strings from different points in a straight line, or when some are on the straight line, and others hanging from it, if the centre of gravity of all the weights be ever in the same vertical with the fulcrum, no motion round the fulcrum can remove it out of that vertical: and all that is necessary to a perfect equilibrium is, that the centre of the weights (that of the machine included) should fall directly under the fulcrum.

The preceding statement rests upon the hypothesis of a system so contrived, that every weight shall hang as it were by a string, and from a straight line, so that all the strings shall approach to, or recede from, the vertical passing through the fulcrum, at the same time and in the same proportion. But if the line from which the weights hang be bent, or if any weight be so attached to the system that it cannot be considered as hanging from a given point, the equilibrium which subsists in one position will not subsist in another. And this, namely, that there should be only one position of equilibrium, is not only required for the use of the instrument, but practically necessary in its construction, as an *indifferent* balance, like that just described, would be difficult of execution.

A balance should be *sensible*, meaning that, when poised, a very small addition of weight to either scale should make it turn—that is, overcome the necessary friction and adhesion of the pivot or knife-edge on which it rests. If there were no friction, the smallest weight would make it turn. The first condition of sensibility, therefore, is the diminution of friction to the utmost possible extent. This is done by making all the parts of a high polish, and by placing the beam upon the support by means of knife-edges attached to its sides. But in order that the knife-edge may not become blunt, the beam is not allowed to rest upon the support except when the instrument is in use; at other times it is raised by two arms which just remove the knife-edge off the support, and these arms can be let down by means of a handle. We shall presently come to the other conditions of sensibility.

A balance should also be *stable*, that is, it should, on being disturbed, immediately return and oscillate about the position of rest. This is done by making the centre of gravity of the whole apparatus fall below the point of support. But as stability is not so difficult to attain as sensibility, the latter must be most attended to. The scales in the shops are sufficiently stable, but few are very sensible.

Neglecting the particular nature of the method of support, and circumstances of mere confirmation, the balance may be represented as follows (see Whewell's 'Elementary Mechanics:')—



C is the point of support, showing a section of one of the knife-edges, which rests upon a smoothly-polished plane; G the centre of gravity of the whole beam, A and B the points of suspension of the scales (which are also usually on knife-edges), D the point of coincidence of AB and CG. The stability of two balances is thus compared. Suppose that the same small disturbance be given to both, say the beam is inclined one degree in both. Then if the force with which the first endeavours to recover its position be double or triple that of the second, the stability of the first is double or triple that of the second. To compare these forces, construct the following formula for both.

To *weight of both scales* $\times$ *CD* add *weight of beam* $\times$ *CG*.

For instance, suppose two balances as follows:—

	First.		Second.
Arm AD	12	.	14 inches.
CD	2	.	3 „
CG	1	.	2 „
Weight of beam	30	.	50 ounces.
Do. both scales	24	.	30 „

Then will the stabilities of the first and second be as $24 \times 2 + 30 \times 1$ to $30 \times 3 + 50 \times 2$, or as 78 to 190.

The sensibility is estimated by comparing the angles through which very small equal weights would incline the balances. If, for example, a grain put into a scale of each inclines the first four degrees, and the second only two degrees, the first is twice as sensible as the second. To compare the sensibilities, multiply the length of the arm of each by the number which represents the stability of the other in the formula just given. Thus the sensibilities of the preceding balances are as 12×190 to 14×78, or as 2280 to 1092.

It would not be worth while to work very accurately by the preceding formula; but the general rules deducible from them are valuable.

1. Other things remaining the same, the longer the arm the greater the sensibility.

2. The arm having a given length, every increase of sensibility is a decrease of stability, and *vice versâ*.

3. Additional weight, either to the scale or beam (the arm remaining the same), is favourable to stability, and unfavourable to sensibility.

4. Whatever does not alter the length of the arm cannot be favourable to both.

In all that precedes, it must be recollected that in the weight of the scales is included whatever may happen to be in them. Consequently every balance has different degrees of sensibility and stability, with the different weights which are employed. But as, generally speaking, the quantities weighed in delicate balances are small, a balance which is highly sensible when no weight is in the scales, will be so for every weight with which it is intended to use it. A balance made by Ramsden for the Royal Society, weighing ten pounds altogether, turned with the ten-millionth of that quantity, or with about the thousandth part of a grain.

A balance should be made as much as possible of brass. Steel and iron are apt to acquire magnetic properties. It should also be inclosed in a glass case, with doors for communication; and, when not in use, a portion of muriate of lime, or any other strong absorbent of moisture, should be placed in the case. A needle is usually attached to the beam, which points either exactly upwards or downwards when the beam is horizontal. A graduated scale of degrees is attached to the frame-work of the instrument, in such manner that the needle may point to zero when it is vertical. The oscillations of the balance, when the centre of gravity is near to that of suspension, will be very slow, and by means of the needle it may be ascertained, before the balance comes to rest, whether horizontal equilibrium has been obtained: for in that case it will describe equal arcs on the graduated scale on each side of the zero point; while if either scale be overloaded, the needle will move through more degrees on the side of that scale than on the other. There are other methods of determining the position of the beams, such as a graduated arc attached to one end of the beam viewed through a compound microscope with a horizontal wire in the focus of the eye-glass, or by a mirror attached to the beam in which the reflected image of a scale is viewed through a telescope.

All that precedes has reference to the theoretical construction of the instrument, and supposes that a perfect balance can be made, so that equal weights shall counterpoise each other. This is certainly impossible in practice, though one balance may be nearer than another. The following simple method, imagined by Borda, overcomes this difficulty, provided only the balance be sensible and very well constructed at the knife-edge. Instead of weighing, say a portion of a salt against brass weights, weigh both the salt and the weights against some third substance, say, for distinction, iron weights, as follows:—call the scales A and B; weigh the salt in A against iron weights in B till there is a counterpoise: then remove the salt and substitute the brass weights in A until there is again a counterpoise. It is now of no consequence whether the weight of iron was equal to that of the salt or not; the weight of the salt and of the brass must be the same, because, under the same circumstances, the two counterpoise the same weight of iron.

Dr. Faraday, in his 'Chemical Manipulation,' sect. ii., gives a number of minute directions on the management of the balance, weighing, &c., to which we refer the student; but we may here select a few details of general interest.

Scientific chemistry may be said to owe its very existence to good balances and accurate weighing. Two or three balances are required in the laboratory; a coarse balance for weighing large quantities, which would injure those intended to show minute differences in small weights, by bending the beam or changing the points of support. This balance should weigh from 1 oz. up to 3 or 4 lbs., or more, and when fully loaded should turn with 2 or 3 grains. A second balance should weigh from $\frac{1}{2}$ a grain to 2 or 3 oz., and turn with about $\frac{1}{2}$ or $\frac{1}{3}$ of a grain when fully loaded; but the best instrument should be capable of weighing from 600 to 1000 grains and downwards, and indicate with distinctness and certainty differences equal to the $\frac{1}{50000}$ or $\frac{1}{60000}$ part of the weight in the scale. The weights required for these balances will vary from 3 lbs. down to the 100th part of a grain, and form at least two sets; the one consisting of averdupois pounds, ounces, drachms, and the other of grains, from 1000 down to the smallest fractions. These weights are usually constructed in sets, containing as few as possible in each; thus, four weights of 1, 2, 3, and 4 grains are sufficient to weigh from 1 to 10 grains; and with similar weights of 10, 20, 30, 40, 100, 200, 300, and 400, as much as 1100 grains can be weighed. A perfect set of weights, from 500 grains down to the hundredths of a grain, should be kept with the best balance. The weights are commonly made of brass, but the smaller ones are of platinum, which is very desirable on account of its unchangeable nature, and the ease with which it may be cleaned without loss, either by wiping, or momentary exposure to the flame of a spirit-lamp.

The vibrations of the balance vary with the load, and as this is increased the slower are the vibrations. To a practised eye, the extent and velocity of vibration indicate nearly the weight required to produce equilibrium. The weight required to produce a certain inclination of the beam, or to turn it, should be known when the balance is slightly as well as heavily loaded. A good balance should turn with the 100th of a grain when 600 grains are in each scale, or with $\frac{1}{60000}$ of the weight to be estimated.

When a balance is overloaded, it is liable to *set;* that is, the side which is lowest becomes permanently depressed. For example, a balance with equal weights in each pan, too heavy for its size, if placed horizontal will remain so; but if one of the pans be a little depressed, it will continue to descend with accelerated force just as if it were the heavier of the two. This effect is more likely to take place in a delicate balance, when overloaded, than in a coarser one. The setting is brought about by the position of the fulcrum below the line which joins the extreme points of suspension of the beam, whereby the centre of gravity of the beam is brought below the fulcrum.

A good method of testing a balance is to remove the pans, and to set the beam vibrating, which it should do in a regular and equable manner, and gradually take up a horizontal position. It should then be reversed on its stand and made to oscillate as before, when, should it again come to rest in a horizontal position, the balance is good; for this test is a severe one, generally disclosing, as it does, some defect in the work of the middle knife-edge, and the planes on which it rests. When the pans are hung upon the beam the balance should still remain horizontal, but the accuracy of the lines of suspension should be tried by changing the pans, then by reversing the beam, and afterwards by changing the pans again. Then put equal weights into the pans, and change them from one pan to another; if the equilibrium be now retained, the lengths of the arms are equal.

The balance was well represented in the Great Exhibition of 1851; so much so as to call for a liberal encomium in the 'Jury Report,' Class X. "When it is considered, in order to have a balance as perfect as possible, how very many circumstances are to be attended to, it must be deemed highly honorable to the exhibitors of good balances to have produced instruments standing the test of the rigorous examination to which they have been subjected."

Among the balances exhibited were some novelties. First, with respect to the modes of suspension. In Mr. Fox's balance, the beam has pivots, the conical ends of which play in hollow agate cones of larger angle.* In the short-armed balance, constructed many years ago by Captain Kater and Mr. Robinson, the then novel feature was the long bearing on which the pans were suspended, instead of the hook and eye arrangement employed on the continent, and in the balances imported into this country. The defects of this arrangement are, that the hook does not always occupy the same position upon the ring with reference to the centre of motion, so that the beam is practically sometimes longer and sometimes shorter, causing differences in the indications of as much as ·01 of a grain. Secondly, the divisions of the scale to which the index of the balance points are numbered 1, 2, 3, &c., to the right and left of zero, to which the index points when the beam is horizontal. It is suggested that the number of the divisions should run the same way, and not begin with zero; it being better to number that division to which the index points when the beam is horizontal, 10, 20, or some multiple of 10, in order to avoid the liability to error consequent upon having positive and negative numbers. Thirdly, in the balances exhibited by Mr. Oertling (a London artist, well known to scientific men for the excellence of his instruments), the beam was in one case coated with platinum, and in another case with palladium: the operation having been performed by Mr. Henry, by some electro-metallurgic process. In Mr. Oertling's large balance, the beam was 3 feet in length, and capable of carrying 56 lbs. in each pan. The beam was a pierced rhomb, constructed so as to give great strength in proportion to its weight, any tendency to lateral yielding being counteracted by edge bars. The three knife edges are long, and the whole length of the middle one rests on a plane surface of steel. Plane surfaces of steel also rest on the extreme knife-edges for suspending the scale-pans. In the second balance, the palladium coated beam is 16 inches long; the three knife-edges, as well as the plane on which the middle one rests, and the planes from which the pans are suspended, are of agate, so that the instrument is not liable to be affected by the acid vapours of the laboratory. In this instrument the beam is graduated, so that small differences of weight can be determined by placing a small platinum wire weight on one of the divisions of the graduated beam. Mr. Marriott exhibited a chemical balance, the beam of which was made of a wide piece of fir-wood, with interstices cut out, so as to leave a strongly-framed net-work; it was said to be sensible to the 100th of a grain. In Mr. Dover's balance, constructed on the plan of Robinson's, the final adjustments in the direction of the length of the beam, and in a direction perpendicular to it, are effected by a cut at each end of the beam, making an angle of about 45° with the axis of the beam, and capable of being widened by means of a screw. In the American balance, capable of carrying 56 lbs. in each pan, the knife-edges are square bars of steel, each fitted into a socket attached to the beam, having a rectangular notch, so that any one of the four edges of the bar may be used as a knife-edge, which would be found useful in case of one of the edges being damaged. The socket in which one of the extreme knife-edges is fixed moves in a slit in the direction of the length of the beam, and is adjusted in that direction by means of two screws. Mr. A. Oertling (Prussia) had a balance in which the knife-edges were let into dove-tail notches in the beam. The adjustment of the distance of the extreme knife-edge from the middle knife-edge was effected by means of a vertical cut in the metal of the beam, capable of being slightly widened or contracted by screws. Fourthly, in some of the French balances the pans were of platinum, suspended by silver wires. Fifthly, there were various contrivances for checking the oscillation of the beam and pans when in action, but none of them were considered by the Jury to be equal to Wollaston's arrangement. In Dolberg's balance (Mecklenburg Schwerin) the oscillation of the pans is checked by hair-brushes which, on turning a handle, ascend, until the ends of the brushes touch the under side of the pan. In Mr. Fox's balance, already mentioned, the attraction of a magnet brings the beam exactly to zero before weighing.

In the measures taken to restore the standards of weight and measure, to replace those which had been destroyed by the burning of the Houses of Parliament, the first step in the process of arriving at the weight of the lost standard was to compare among themselves the different troy pounds with which the lost standard had been compared by Captain Kater and Captain V. Nehus. The balance used for these comparisons was furnished by Mr. Barrow, on Robinson's principle, and is described by Professor W. H. Miller, in his paper in the 'Philosophical Transactions' for 1856, 'On the Construction of the New Imperial Standard Pounds,' &c. "The beam is made sufficiently strong to carry a kilogramme in each pan. The middle knife-edge is about 1·93 inch long, and rests, when the balance is in action, throughout its whole length on a single plane surface of quartz. The surfaces of quartz which rest upon the extreme knife-edges, and from which the pans are

* In the balance constructed under the direction of Gauss and Weber ('Gottengen Transactions'), the beam is suspended by two watch-springs, and each pan by a single watch-spring. In Steinheil's balance the beam and pans are suspended by wires or silk ribbons: or by another method the beam carries two small steel spheres in the middle, resting upon a steel plane, while at each end of the beam is a sphere, upon which rests either the plane or the slightly concave spherical surface of the plate from which the scale-pan is suspended. None of these balances were exhibited.

suspended, are also plane. The distance between the extreme knife-edges is about 15·06 inches, the length of each about 1·05 inch. Instead of having an index pointing downwards, as is usual in balances of this description, the beam has a pointer at each end, and a graduated scale is carried by an arm attached to the pillar of the balance at a little distance behind the left-hand pointer. Affixed to the right-hand end of the beam is a thin slip of ivory, a little more than half-an-inch long, divided into spaces of about 0·01 inch each, or subtending an angle of about 5′ each at the middle knife-edge. This scale is viewed through a compound microscope, having a single horizontal wire in the focus of the eye-piece. The distance between two divisions of the scale, as seen through the microscope, subtends an angle of 37′. This contrivance for determining the position of the beam at the extremity of an oscillation was found so superior to a scale and pointer viewed with the naked eye, that after a trial of a few days, the scale at the left hand was found to be a useless incumbrance, and was accordingly removed. A screen was interposed between the observer and the front of the balance-case, having a small opening opposite to the eye-piece of the microscope, through which the scale could be seen."

BALANCE OF POWER. The notion upon which this phrase is founded appears to be the following. When a number of separate and sovereign states have grown up beside each other, the entire system which they constitute may be conceived to be *in equilibrio*, or evenly balanced, so long as no single one of them is in a condition to interfere with the independence of any of the rest.

But as in such a system of states so connected there are generally a few which may be considered as leading powers, it is by these being being made to counterpoise each other that the balance is principally maintained. It is in this way only that the safety of the smaller states can be secured. Thus, in the ancient world, after the destruction of Carthage, there was no power any where left strong enough to cope with Rome; and the consequence was, that, one after another, the countries that yet remained sovereign powers fell under her dominion, until she became the mistress of the ancient world.

On the contrary, so long as the power of one great state (however far surpassing in extent of territory, or other resources of strength and influence, many of those in its neighbourhood) can be kept in check, or, in other words, balanced by that of another, the independence of the smaller states is secured against both. Neither will be disposed to allow its rival to add to its power by the conquest or absorption of any of these minor and otherwise defenceless members of the system. And in this way it happens that each state, whether great or small, has an interest and a motive to exert itself in the preservation of the balance.

This point of policy is so obvious, that it must have been acted upon in all ages, by every assemblage of states so connected or situated as to influence one another. There may have been less or more of skill or wisdom in the manner of acting upon it, or the attempt to act upon it may have been more or less successful, in different cases; but to suppose that its importance had been overlooked by any states that ever existed in the circumstances described, would be to suppose such states to have been destitute of the instinct of self-preservation.

Hume (see his 'Essays,' part ii. essay 7th) has shown conclusively, in opposition to the opinion sometimes expressed, that ancient politicians were well acquainted with the principle of the balance of power, although, as far as appears, they did not designate it by that name. "In all the politics of Greece," he observes, "the anxiety with regard to the balance of power is apparent, and is expressly pointed out to us even by the ancient historians. Thucydides (lib. i.) represents the league which was formed against Athens, and which produced the Peloponnesian war, as entirely owing to this principle; and after the decline of Athens, when the Thebans and Lacedæmonians disputed for sovereignty, we find that the Athenians (as well as many other republics) always threw themselves into the lighter scale, and endeavoured to preserve the balance. They supported Thebes against Sparta, till the great victory gained by Epaminondas at Leuctra: after which they immediately went over to the conquered—from generosity, as they pretended, but, in reality, from their jealousy of the conquerors." "Whoever," he adds, "will read Demosthenes' oration for the Megalopolitans, may see the utmost refinements on this principle that ever entered into the head of a Venetian or English speculatist." He afterwards quotes a passage from Polybius (lib. i. c. 83), in which that writer states that Hiero, king of Syracuse, though the ally of Rome, yet sent assistance to the Carthaginians, during the war of the auxiliaries, "esteeming it requisite, both in order to retain his dominions in Sicily, and to preserve the Roman friendship, that Carthage should be safe; lest by its fall the remaining power should be able, without contest or opposition, to execute every purpose and undertaking. And here he acted with great wisdom and prudence; for that is never on any account to be overlooked; nor ought such a force ever to be thrown into one hand as to incapacitate the neighbouring states from defending their rights against it." "Here," remarks Hume, "is the aim of modern politics pointed out in express terms."

It must be confessed, however, that the preservation of the balance of power was never so distinctly recognised and adopted as a principle of general policy in ancient as it has been in modern times. The systematic observance of the principle of the balance, subsequently to the subversion of the Roman empire, may be first traced in the conduct of the several Italian republics. It appears clearly to have formed part of what may be called the public law of these rival sovereignties from about the commencement of the 15th century. From the commencement of the next century it became an influencing principle in the general policy of Europe.

The leading rule by which it has ever since then been attempted to maintain the balance in question, may be stated to be the opposing of every new arrangement which threatens either materially to augment the strength of one of the greater powers, or to diminish that of another. Thus, first Austria, and afterwards France, have been the great objects of the jealousy and vigilance of the other states of Europe. While the supremacy of the Empire was united in the person of Charles V. to the monarchy of Spain, that province was naturally regarded as formidable both by France and England. If he could have effected a permanent alliance with either of these powers, or could have even induced one of them to stand aside and acquiesce, there can be little doubt that he would have taken that occasion to attempt to crush the other. The vast possessions of Philip II. appeared to call for the same watchfulness and opposition in regard to his projects, from all other states that valued their independence. In later times, the ambition of Louis XIV. of France, and the scheme concerted under his management to unite in one family the crowns of France and Spain, drew upon him, in like manner, the general hostility of Europe. There can be no manner of doubt, that, if the designs of this sovereign had not been thus resisted, France would have become a century earlier than it did the mistress of the continent, and the independence of all other nations would, for a time at least, have been extinguished. Our own liberties, as founded upon the Revolution of 1688, could, in such circumstances, certainly not have been maintained.

It is nothing to the purpose to argue that the maintenance of the balance of power has often involved the nations of Europe in contests with each other, which, if they had disregarded that principle, would not have taken place, at least, not at the time. It may be better that all nations should be subject to one, than that each should preserve its independence; but that is not the question here: if nations will be sovereign and independent, they must fight for their sovereignty, as men must do for any other possession, when it is attacked.

But some persons appear to think that we in this country have nothing to do with the maintenance of the so-called balance of power in Europe, because we live not on the continent, but in an island by ourselves. If the whole continent were reduced under subjection to a single despot, we certainly should not long remain independent. The protection which we now possess from the sea with which we are surrounded would, in the case supposed, certainly become insufficient. The water alone would not keep off an enemy, if we had not a navy to ride on it; and we could not maintain a great navy without our foreign trade; which, with all the rest of Europe united under one head against us, certainly could not subsist.

The maintenance of the principle of the balance of power, however, although it has no doubt given occasion to some wars, has probably prevented more. Its general recognition has, to a certain extent, united all the states of Europe into one great confederacy, and habituated each of the leading powers to the expectation of a most formidable resistance in case of its making any attempt to encroach upon the rights of its neighbours. It is not sufficient objection to say that such attempts have been actually made. They would have been made much oftener had there been no such general understanding as we have spoken of. It must have operated as a great discouragement and check to the schemes of ambitious potentates, to know that, from the first consolidation of the modern European system down to the partition of Poland in 1772—a period, we may say, of three centuries—not the smallest independent state had suffered extinction, or had been even very seriously curtailed of power or territory, notwithstanding all the wars for the purpose of conquest and aggrandisement that had been waged during that long interval.

BALANCE OF TRADE. In a tract published in 1677, called 'England's Great Happiness,' which is quoted by Mr. M'Culloch in the introductory discourse to his edition of Smith's 'Wealth of Nations,' is the following dialogue between "Complaint" and "Content:"—

"*Complaint.* What think you of the French trade which draws away our money by wholesale? Mr. Fortrey gives an account that they get 1,600,000*l.* a year from us.

"*Content.* 'Tis a great sum; but, perhaps, were it put to a vote in a wise council, whether for that reason the trade should be left off, 'twould go in the negative. I must confess I had rather they'd use our goods than our money; but if not, I would not lose the getting of ten pounds because I can't get an hundred. . . . I'll suppose John-a-Nokes to be a butcher, Dick-a-Styles to be an exchange-man, yourself a lawyer,—will you buy no meat or ribands, or your wife a fine Indian gown or fan, because they will not *truck* with you for indentures which they have need of? I suppose no; but if you get money enough of others, you care not though you give it away in specie for these things. I think 'tis the same case."

The year after this sensible and conclusive passage was written, the French trade was prohibited for three years; and in the reign of

William III. the legislature voted the French trade a nuisance, and made the prohibition perpetual. This was to enforce what was called a favourable balance of trade. The notion, we thus see, was not a vague theory, but a mischievous rule of practice, which even in our own time some people regarded with admiration, and would eagerly have laboured to make it a part of our commercial code. They would have the nation to be the lawyer who wants to *truck* his indentures with the wine-merchant; but because the wine-merchant will not have the indentures, the lawyer ought, according to this, to go without the wine, although he might *sell* the indentures to the exchange-man, who would thus furnish him with the specie for buying the wine.

The balance of trade, as understood by those who adopt the theory, is the difference between the aggregate amount of a nation's exports or imports, or the balance of the particular account of the nation's trade with another nation. If the account shows that the imports (valued in money) exceed the exports (valued also in money), the balance is said to be against the nation; if the exports exceed the imports, the balance is said to be in the nation's favour. This mode of estimating the so-called balance is evidently founded on the assumption that the precious metals constitute the wealth of a country;—when the imports from any country, as valued in money, exceed the exports to the same, also valued in money, the exporting country must part with some of its precious metals in payment; and, according to the doctrine, must so far lose by the trade. The nation had not the means of keeping very clear accounts of these matters, for it had an arbitrary standard of value, called *official*, which had been in use for nearly a century and a half, and which *official value* was an ingenious device for perplexing many otherwise simple questions, and for keeping up many absurd prejudices. Now, taking these official or unreal values in connexion with the device of the balance of trade, we find that during the year 1833 the United Kingdom gained some thirty-four millions sterling by a favourable balance; for its imports, or the goods it received from foreigners, amounted to forty-five millions, whilst its exports, or the goods it sent to foreigners, amounted to seventy-nine millions. In 1832 the same sort of excess amounted to thirty-two millions, and in 1831 to twenty-two millions. If the favourable balance of these three years were anything but a fiction, it is manifest that the nation would, in these three years only, have accumulated specie to the extent of the favourable balance, and this would amount to the sum of eighty-eight millions sterling. But, further, the same favourable balance has been going on for the last half century, or longer; and the result would be, that all the specie in the world would at the present time be locked up in this island, and that the balance of thirty-four millions in 1833 would only be a small addition to the heap. Such a result is impossible, for bullion is as much a commodity for sale as corn, and is consequently as generally exchanged. [BULLION.] But if this result were possible, and a nation resolving to sell only for specie, as the Chinese affected to do with regard to tea, could have the power of selling only for specie, this power of turning all its goods to gold, like the same power bestowed upon the wise king Midas, would confer the privilege of being without food, and clothes, and every worldly comfort upon the unhappy inhabitants of such a nation. The truth is, that no commerce is of any value to a country except as it gives the people of that country the power of consuming foreign productions, which they either cannot produce at all at home, or which are produced cheaper and better abroad. It is the power of *exchanging* the surplus produce of one country for the surplus produce of another country which constitutes the ultimate object of all foreign commerce. The profit of the individual merchant is the moving force which impels the machinery of this commerce, but the end is, that each country may consume what it would otherwise go without. In this point of view, every country is a gainer by its foreign commerce; and if this gain could be estimated by figures, every country which exchanges its products with another country would have a favourable balance of trade: for both individuals and nations exchange that which they do not want for other things that they do want; and when both parties continue to carry on such exchange, it is clear that both are gainers. Which gains most is a question that cannot be settled, and would be of no use if it could be settled.

BA'LCONY is derived from the Italian word *balco*, or *palco*. ('Dizzionario della Crusca.') Balcon is often used by Boccaccio in his 'Novelle,' from which circumstance we may conclude that balconies were common in Italy at that time. Palco signifies, in Italian, the box of a theatre; and in the great theatre at Bologna, built, we believe, by Palladio, each box or balcony has a balustrade. [BALUSTRADE.] The balcony has been much employed in modern edifices. The object of balconies is to give the inhabitants of a house a better view. They are formed nearly on a level with the floors of rooms, and supported on cantilevers or brackets, and sometimes, though more rarely, on columns of wood or stone. The floor of the balcony is laid on the cantilevers, and the sides are inclosed with a rail of iron, or a balustrade of stone. Where balconies are formed, the windows are for the most part made to open down to the ground. In London cast-iron railing, variously designed, is most commonly used. There are, however, balconies with balusters of stone sometimes placed before single windows, or continuous ranges of them. The Goldsmiths' Hall, at the back of the Post-office, is an example of the former; the Crescent at the end of Portland-place, of the latter. Some balconies have a very slight projection, and rest not upon cantilevers, but upon the basement wall, as in the Banqueting-house at Whitehall. In Venice there are very magnificent Gothic balconies remarkable for their richness. It is uncertain when balconies were first introduced into England. Some of the old inns, with the galleries round them, are perhaps the oldest examples existing. Elizabethan architecture shows some very elaborately designed balconies; but perhaps the nearest example to the *palco* of the Italians will be found in some of the colleges of Oxford. Magdalen College contains an example of such a balcony in a pulpit supported on corbels.

BA'LDACHIN (*Baldachino*, Italian), a kind of canopy, either supported on columns, or suspended from, and used to cover an altar in a Roman Catholic church. The word is derived from the Italian *baldachino*, signifying a piece of furniture, which is carried, or which is fixed, over sacred things, or over the seats of princes and persons of great distinction, as a mark of honour. The form, for the most part is square, and the top covered with cloth with a hanging fringe: sometimes the fringe is formed of pieces of cloth cut out after the fashion of a banner. The baldachin has been supposed to have been derived from the ancient *ciborium* (*κιβώριον*, a large cup or vase). An isolated building, placed by the early Christians over tombs and altars, was called a ciborium. The modern baldachin is of the same form as the ciborium erected by Justinian in the church of Santa Sophia at Constantinople, which was made of silver, gold, and precious stones, and supported by four silver-gilt columns. The baldachin is however deprived of the curtains which in the ciborium were intended to inclose whatever was deemed sacred within. ('Encyclopédie Méthodique.') The Mohammedans seem to have copied the ciborium in their tombs. (See the domed tombs at Cairo, in the work of the French Institute on Egypt.) The baldachin carried over the host in Roman Catholic countries is not unfrequently of an umbrella shape; a similar sort of umbrella may be seen on an Etruscan vase. (Millingen 'Vases.')

The baldachin in St. Peter's at Rome, made by Bernini, is the most celebrated, and is the largest known work of the kind in bronze. The dais, or covering, is supported on four large twisted columns of the composite order, placed upon pedestals of black marble, the dies of which are ornamented with bronze escutcheons. The columns are fluted for one-third of their height; the remaining part is ornamented with bays and leaves of laurel, combined something after the manner of the columns of the temple designed by Raffaelle in one of his cartoons. The whole work is beautifully executed and highly-finished. Above the columns are four figures of angels standing upright; at the top of the covering there is a cross, and below the entablature the banner-like cloth fringe of the portable baldachin has been imitated. The plan is square, and the altar stands between the two pedestals of the foremost columns. The height is 126 ft. 3 in. from the floor of the church to the summit of the cross, of which the pedestal is 11 ft. 8 in., the columns 50 ft. 4 in.; the entablature 11 ft. 6 in., the covering 40 ft., and the cross is 12 ft. 9 in. There were 186,392 lbs. of bronze employed on this work; the chasing alone cost more than 100,000 crowns. The Pantheon was despoiled of its fine bronze ornaments to form this baldachin, and there being more ornaments than were necessary, the remainder were afterwards cast into cannon.

The baldachin of Santa Maria Maggiore, the next in importance to that of St. Peter's, is a kind of crown supported by four figures standing on columns of porphyry ornamented with bands of bronze. It was made by the Cavaliere Fuga. It is not improbable that the Gothic canopies [CANOPY] over figures of saints and personages of distinction, were intended for baldachins, as they appear to be used as marks of distinction, and not for a covering only to protect them from the weather, as they are placed horizontally on the tombs of kings and queens, and other personages of high rank. (See the tombs of the kings in Westminster Abbey, and the engravings in Stothard's 'Monumental Remains;' Blore's 'Monumental Remains of Great Britain,' &c.)

BALDRICK, or BAUDRICK (Fr., *baudrier*), the military belt, band, or girdle, much used by warriors in more ancient, as well as in the feudal times; encircling the waist, or pendant from the right shoulder, and usually sustaining a sword: was sometimes called a baldrick, but the baldrick seems to have differed from the military belt by being uniformly worn over the shoulder and across the breast, and from it a sword was not always slung. Menage derives this word, through the medium of the low Latin *baldringus*, from the Latin *balteus*. Ducange derives it through *baldrellus*.

The figure of William de Valence, Earl of Pembroke, in Westminster Abbey, has a belt finely enamelled with his coat of arms. Various arms are also enamelled on the belt of Edmund Crouchback, Earl of Lancaster's figure in the same church. The effigy of Geoffrey de Magnaville, in the Temple Church, has both a belt and a baldrick, while that of William Longespee has a belt only. But Spenser, in his 'Faerie Queene' (book i. canto vii.) makes Una to meet a "goodly knight," and—

> "Athwart his breast a bauldrick brave he ware,"

While—

> "Thereby his mortal blade full comely hong."

Chaucer, on the contrary, says of the yeoman, the squire's attendant, that—

> "An horne he bore, the baudrick was of grene;"

And Drayton, in his 'Polyolbion,' speaking of Robin Hood and his followers, has—

> "Their bauldricks set with studs, athwart their shoulders cast,
> To which, under their arms, their sheafs [quivers] were buckled fast,
> A short sword at their belt."

The 'Lytell Geste of Robyn Hode,' however, makes no mention either of baldricks or belts.

BALDWIN'S PHOSPHORUS. This substance consists of fused nitrate of lime, which, after exposure to the direct solar rays, continues to emit a phosphorescent light for several hours after it has been placed in a darkened room. This apparent absorption and subsequent emission of light is accompanied by no chemical change, and is consequently a purely physical phenomenon.

BALENIC ACID ($C_{38}H_{37}O_3HO$)? A fatty acid said to have been found in whale oil, but its existence is very doubtful.

BALISTÆ. [ARTILLERY.]

BALLAD, in music, a short air, repeated to two or more stanzas, simple in construction, therefore confined in modulation, and having an accompaniment of a strictly subordinate kind. When an air, or its accompaniment, is florid, or modulates into unrelated keys,—when, in short, either assumes a more elaborate form, the composition generally takes the name of *song*, or *canzonet*, even when several stanzas are repeated to the same melody. [SONG; CANZONET.]

BALLAD, in poetry, a popular song or roundelay, generally sung or chanted. Johnson, in his dictionary, defines a ballad as a song; and the words are very often used as synonymous. It is not perhaps very easy to define the ballad as distinguished from the song, because in the course of many centuries it has embraced many species of poetry. As our old ballads were chanted, the name of ballad-singer became in course of time applied to everything sung in the street; but the distinction between a ballad and a song, if any, is that the ballad has more of the epic character, the song more of the lyric. The first must contain a narrative, or at least relate to man and his actions; the second may embody only a sentiment or description. The 'Dictionnaire de l'Académie Française' defines the ballade as a species of ancient French poetry, composed in couplets, and which must contain three couplets and an envoi; and a prior of St. Genevieve at Paris, about the middle or latter half of the 15th century, wrote a system of rules for ballad writing, 'L'Art de Dictier Ballades et Rondelles,' which Warton terms the first Art of Poetry printed in France. Bishop Percy says, the English word ballad is evidently from the French *ballade*, as the latter is from the Italian *ballata*; which the Crusca dictionary defines 'Canzone che si canta ballando,' a song which is sung during a dance. But he adds that the word appears to have had an earlier origin: for in the decline of the Roman empire, these trivial songs were called *ballistea* and *saltationes*. "Ballisteum," Salmasius says, "is properly *ballistium*, Gr. *βαλλιστεῖον, ἀπὸ τοῦ βαλλίζω*. . . . . *βαλλιστία saltatio*. . . . . *Ballistium* igitur est quod vulgo vocamus *ballet*; nam inde deducta vox nostra." (Percy, 'Rel. of Anc. Eng. Poet.' 8vo, 1794, vol. i. p. xcviii; Salmas. 'Not. in Hist. Aug. Script.' vi. p. 439.)

Ballads and rude poetry have been, in all countries, the earliest memorials of public transactions; and in the savage state of each were invariably used to rouse and perpetuate a martial spirit. Tacitus tells us that Arminius, long after his death, was remembered in the rude songs of his country ('Annal.' ii. 88); and the same writer informs us that ballads were the only annals known among the ancient Germans. They have a tradition, he adds, that Hercules visited those parts, and they sing his praises, when rushing to battle, in preference to all other heroes. ('De Morib. Germ.' sect. ii., iii.) Saxo Grammaticus, speaking of the Northern writers of a somewhat later period than this, says they drew the materials of their history from Runic songs. The Scandinavians had their Scalds, whose business it was to compose ballads, in which they also celebrated the warlike achievements of their ancestors. Similar panegyrists of warrior-merit existed in Gaul, Britain, Wales, and Ireland; and it must not be forgotten that when Edward I. formed the plan of reducing Wales to subjection, he thought it necessary to destroy the bards. Their compositions, however, survived; and a writer as late as Queen Elizabeth's time, describing North Wales, says, "Upon the Sundays and holidays the multitude of all sorts of men, women, and children of every parish do use to meet in sundry places, either on some hill or on the side of some mountain, where their harpers and crowthers sing them songs of the doings of their ancestors." (Ellis, 'Orig. Lett. of Eng. Hist.' 2nd ser., vol. iii. p. 49.) Even in the New World, the American savages had their war-songs and rude poetry, in which they sung the praises of those who had fought and died for their country. Garcilasso de la Vega says, that in writing his history of Peru he availed himself of old songs and ballads, which a princess of the race of their Incas taught him to get by heart in his infancy.

In process of time, as manners refined, the ballad in every country by degrees included a wider range of subjects; it was no longer solely employed in rehearsing valorous deeds, but included in its rhymes the marvellous tale or the wild adventure, occasionally also becoming the vehicle of sentiment and passion; and no festivity was esteemed complete among our ancestors in the 11th, 12th, and 13th centuries, which was not set off with the exercise of the minstrel's talents, who usually sang his ballad to his own or some other. harp, and was every where received with respect.

As intellectual cultivation advanced, however, these rude performances gradually lost their attraction with the superior ranks in society; but in the further progress of literary taste, they came to be considered as objects of curiosity, on account of the insight they afforded into the manners and modes of thinking of remote times; while the strokes of nature with which they abounded, and the artless simplicity and strength of their language excited the admiration of liberal critics. When, therefore, they had long ceased to be current in popular song or recitation, they were carefully collected by poetical antiquaries, and elucidated by historical notes; and thus a secondary importance was attached to them scarcely inferior to that which they possessed when chanted to the harp of the minstrel. (See Aikin's 'Essay prefixed to his Vocal Poetry,' 8vo. London, 1810.)

Among numerous other collections of our own national ballads, Percy's 'Reliques;' Evans's 'Old Ballads, Historical and Narrative;' and Ritson's 'Ancient Songs from the time of Henry III.' stand conspicuous. Allan Ramsay, Pinkerton, Jamieson, Finlay, and Aytoun have collected the 'Scottish Ballads;' and Sir Walter Scott the particular 'Minstrelsy of the Scottish Border.' Of those of other countries we cannot omit the Spanish ballads so frequently quoted by Percy from 'Hist. de las Civiles Guerras de Granada,' Madr. 1694; and the 'Coleccion de Poesias Castellanas anteriores al Siglo XV.,' by D. Tomas Antonio Sanchez, 3 vols. 8vo. Madr. 1779; among the Italians the 'Canti Carnascialeschi' of the time of Lorenzo de' Medici, 8vo. 1559; and among the ancient ballads of the North, the 'Altdänische Heldenlieder, Balladen, und Mährchen, übersetzt von Wilhelm Carl Grimm,' 8vo. Heidelb., 1811. More recent are the 'Danske Viser,' of Abrahamson and Rahbek; and the 'Svenska Fornsänger,' of A. I. Arwiddson, in 1842. St. Cæsari and the monks of Hières collected the remains and biographies of the minstrels of Provence; and the canon Manesse those of the Swabian poets.

As Ritson says, there can be no doubt that a considerable number of our own ancient printed songs and ballads must have perished. Few exist of an earlier date than the reign of James, or even of Charles I. Being printed only on single sheets, which would fall chiefly into the hands of the vulgar, who had no better method of preserving their favourite compositions than by pasting them upon the wall, their destruction is easily accounted for. The practice of collecting them into books did not commence till after Queen Elizabeth's time, and is probably owing to Johnson and Delaney (great ballad-mongers), who when they were advanced in years, and incapable, perhaps, of producing anything of merit, seem to have contented themselves with collecting their more juvenile or happier compositions into little penny books, entitled 'Garlands;' of these, being popular, and often reprinted, many are still extant, particularly in the Pepysian library. ('Diss. on Ant. Songs and Music,' p. lxxii.)

The earliest English ballad is that on the defeat of De Montfort in the battle of Evesham, but it is written in Norman French, though thoroughly English in sentiment and feeling. The next earliest ballads are those of the genuine Robin Hood series, particularly the 'Lytell Geste,' a series that may well bear comparison for truth and feeling, with a considerable share of English humour, with those of the Spanish Cid, however different in character. And we believe that England and Scotland are richer than any other nation in Europe, not even excepting Spain, in true original popular ballad poetry, as distinguished from lyrical effusions; a fact probably arising from the free nature of their constitution, which has ever been gradually and surely developing itself from the time of the Norman conquest, and the consequent active exercise of the public mind in the discussion of all passing events. They are, moreover, markedly distinguished from those of Spain by a sense of personal independence, and by a frequent selection of persons of low rank as the heroes of great achievements. The ancient ballads of Germany are also marked by national peculiarities; those composing the Niebelungen Lied having more resemblance to those of the Cid than to the English ballad, in treating of high historical, but half or more than half fabulous, events, rather than of the social manners, habits, and feelings of the populace. Those of Hans Sachs had more of these latter qualities, but they were not of any distinguished literary excellence, and indeed are hardly to be called ballads. In modern ballad-writing Bürger, Schiller, Göthe, and Uhland have given many admirable specimens.

The earliest specimen of Scottish song, after the Scots spoke the English language, is preserved in the 'Rhyming Chronicle' of Andrew Wyntown, prior of Lochleven, written, as is generally supposed, about the year 1420, in which he relates the song which was made on Alexander III. who was killed by a fall from his horse in 1286. Ritson has given it in the 'Hist. Essay' prefixed to his 'Scottish Songs,' vol. i. p. xxiv.

The earliest English ballad, separately printed upon a single sheet, is believed to be one upon the downfall of Thomas Lord Cromwell, in 1540.

The ballad, as distinguished from song, has been successfully cultivated by modern English writers. Wordsworth, Southey, Scott, and still later Mr. Browning, Lord Macaulay in his ballads of Montcontour and Ivry, and his 'Lays of Ancient Rome;' and Mr. Aytoun in his 'Lays of the Scottish Cavaliers,' have shown that the spirit, fidelity, and vigour of the old ballad-writers of Britain have not altogether departed. The ballad has given its name to a peculiar metre, which is that used in the old ballad of Chevy Chase; but that metre has not, by modern authorities, been held as a necessary constituent of a ballad.

BALLAST (Danish, *Baglast;* German, Dutch, and Swedish, *Ballast;* French, *Lest;* Italian, *Savorra;* Spanish, *Lastre;* Portuguese, *Lastro;* Russian, *Balast*), a term used to denote any heavy material placed in a ship's hold with the object of sinking her deeper in the water, and of thereby rendering her capable of carrying sail without danger of being overset. Ships are said to be in ballast when they sail without a cargo, having on board only the stores and other articles requisite for the use of the vessel and crew, as well as of any passengers who may be proceeding with her upon the voyage. In favour of vessels thus circumstanced it is usual to dispense with many formalities at the custom-houses of the ports of departure and entry, and to remit the payment of certain dues and port charges which are levied upon ships having cargoes on board.

A foreign vessel proceeding from a British port may take on board chalk as ballast, and shall not be considered as other than a ship in ballast, in consequence of her having on board a small quantity of goods of British manufacture for the private use of the master and crew, and not by way of merchandise; but such goods must not exceed in value 20*l.* for the master, 10*l.* for the mate, and 5*l.* for each of the crew.

Regulations have at various times been made in different ports and countries, determining the modes in which ships may be supplied with ballast, and in what manner they may discharge the same; such regulations being necessary to prevent injury to harbours. It has likewise been sometimes attempted to convert the supply of materials for ballast into a monopoly. In vol. xx. of Rymer's 'Fœdera,' p. 93, of the year 1636, we find a proclamation by King Charles I., ordering "that none shall buy any ballast out of the river Thames but a person appointed by him for that purpose;" and this appointment was sold for the king's profit. Since that time, the soil of the river Thames, from London Bridge to the sea, has been vested in the corporation of the Trinity House, and a fine of 10*l.* may be recovered from any person for every ton of ballast which he may take out of the river, within those limits, without the authority of that corporation.

The ballast of all ships or vessels coming into the Thames must be unladen into a lighter, and if any ballast be thrown into the river, the master of the vessel whence it is thrown is liable to a fine of 20*l.* Some regulation similar to this is usually enforced in every port.

Some art is required in properly ballasting a ship. The quantity required by different vessels of the same tonnage varies according to their shape or build. If any great quantity of heavy ballast, such as lead or iron, is deposited in the bottom of the hold, the centre of gravity will be placed so low that the vessel will labour and roll violently in the sea, and in bad weather will be in danger of being dismasted: it will besides impair her sailing qualities. A ship thus ballasted is said to be too stiff. On the contrary, when a ship has too little ballast, or this is so disposed as to raise the centre of gravity too high, equal danger will arise: she is then said to be too crank. The art of properly ballasting ships consists in placing the centre of gravity so as to be neither too high nor too low, and as this will in a great measure depend upon the shape of the vessel, it is not possible to give any particular directions concerning it, but the task should be confided to experienced hands.

A ship, being under proper and convenient sail, is said to be in 'sailing trim' when the ballast (or cargo) is so disposed, both before and abaft the ship's centre, as to incline her head to approach more nearly the point from which the wind blows: this is called *luffing up into the wind*, and in such case the ship is said to need or carry a little *weather-helm.* Errors in the mode of ballasting or trimming a ship can generally be remedied by increasing or diminishing the quantity of head or after sail.

Ships that take on board cargoes of light goods require also some portion of ballast in order to lower them sufficiently in the water, and by adjusting the centre of gravity, to enable them to carry with safety the necessary press of sail. [FREIGHT.]

By the Mercantile Marine Act of 1854, ballast rates, together with lighthouse tolls, &c., are to form the 'Mercantile Marine Fund.' [LIGHTHOUSE.]

The most important use of ballast in relation to English shipping is, probably, in the colliery trade; owing to the fact, that the vessels which bring coal to London have very little cargo to take back to the Tyne, Wear, and Tees. There are five systems of collier-ballasting adopted: sand ballast, bag-water ballast, bottom-water ballast, hold-water ballast, and tank-water ballast. The first three are employed in ordinary sailing colliers, the fourth and fifth being more exceptional. *Sand ballast* was the earliest, easiest, and most obvious. *Bag-water ballast* was invented by Dr. White, of Newcastle, and was found to be cheaper in the end than sand. The bags are arranged on the floor of the vessel, and are connected with a canvas hose; this hose, through the intervention of a large stop-cock, communicates with the water outside the vessel; to fill the bags, the cock is simply turned; to empty them, the water is allowed to flow into the hold, whence it is pumped out with the bilge-water. *Bottom-water ballast* consists of water filling the intermediate space between the true bottom and a false bottom of the vessel. *Hold-water ballast* is contained in an iron water-hold placed amidships, and capable of containing 200 tons or more. The hold is so constructed, with a hatchway, &c., as to be available for cargo when not filled with water-ballast. These ballast water-holds were first adopted by Mr. Scott Russell, in two iron screw colliers built by him. *Tank-water ballast* is used in the following way: a series of fore-and-aft tanks are supplied with water from a tank in the fore-peak, and the discharge is effected by pumps worked by a small auxiliary engine. Engineers and persons engaged in the colliery trade are not yet agreed as to the relative merits of these five kinds of ballasting; but there is a general agreement that sand ballast will be, and ought to be, superseded by water.

(Hume's *Laws of the Customs; Report of Committee of House of Lords on Lights and Harbour Dues;* Mortimer's *Dictionary;* M'Culloch's *Dictionary.*)

BALLAST-OFFICE CORPORATION, DUBLIN, or more correctly, the Corporation for Preserving and Improving the Port of Dublin. This Board was created, in 1786, by the Act 26 Geo. III. c. 19 of the Irish parliament, and consists of twenty-three members, namely: "The lord mayor and sheriffs, for the time being, of the city of Dublin, three aldermen, chosen by the Board of Aldermen from their own body, and seventeen members who were appointed, in the first instance, by the Act of Incorporation, and who are, on all future vacancies, empowered to elect new members, but leaving the city members as members of the Board."

This self-elected body is endowed with extensive powers to enable it to carry on the works and to improve the port of Dublin; besides which, it has an exclusive right, similar to that exercised by the Corporation of the Trinity House in London, of supplying with ballast all vessels sailing from the port of Dublin. In 1810 the management of all the light-houses on the coast of Ireland was transferred from the Commissioners of Customs to the Ballast-Office Corporation in Dublin, which, however, exercises this part of its duty subject to the control and direction of the elder brethren of the Trinity House in London.

The Ballast-Board has greatly improved the port of Dublin, by re-building the walls of the river Liffey, and by deepening its channel. In the beginning of 1834 a very extensive work of the latter kind was undertaken, in the execution of which powerful steam machinery has been employed. Since 1820 the Board has expended, for the erection of light-houses and the building of floating-lights, a very large sum, which has been defrayed out of the surplus dues.

BALLET, a theatrical representation, in which a story is told by gesture, accompanied by characteristic or illustrative music, and to which dancing (as mere saltation), scenery, decorations, &c., are the accessories.

We are indebted for the word, and even for its pronunciation, to the French, who had it from the Italian, *ballare,* to dance; the latter having been derived from βαλλίζειν, which has the same meaning.

The French enumerate three kinds of *ballet,* namely, the *ballet d'action,* or *ballet-pantomime;* the *opéra-ballet;* and the *comédie-ballet.* The two last are not now in use: the first is that above described, and the only true ballet; for those which consist of little else than steps, leaps, *pirouettes,* and *entrechats,* are unworthy of the name, and in fact are *divertissemens,* in which, as Rousseau remarks, there is no subject, no connection, and the best performers tell you nothing, but that they dance well.

"A ballet," says M. Noverre, who by Garrick was called 'The Shakspere of Dance,' "perfect in all its parts is a picture, drawn from life, of the manners, dresses, ceremonies, and customs of all nations. It must therefore be a complete pantomime, and through the eyes speak to the very soul of the spectator; and being a regular representation, ought, as far as is possible, to be under the general rules of the drama. If it does not point out with perspicuity, and without the aid of a programme, the passions and incidents it is intended to describe, it is a divertissement, a succession of dances, and nothing better." ('Lettres sur la Danse,' Lyon, 1760.)

Appropriate music is a constituent part of a good ballet; it supplies the language which action alone cannot speak, and is grave or lively, energetic or tender, according to the passion or sentiment meant to be pourtrayed on the stage. By its rhythm it also regulates the motion of the dancer (for all the performers in the ballet are indiscriminately called dancers), whose every action and step ought to be more or less measured. Aristotle, in his 'Poetik' (cap. iii.), goes so far as to say, that there are dancers who by rhythm applied to gesture express manners, passions, and actions. A composer of good ballet-music is carefully attentive to locality and to nationality. Almost every civilised nation has, in addition to a general style of melody, a style peculiarly its own; and by a judicious adoption of this, an incalculable addition is made to the interest and the reality of the scene, through the powerful medium of association. Gluck did not hesitate to introduce, in his 'Iphigenia in Tauris,' the real air of a cannibal nation, to which he made certain barbarians dance. The occasional and cautious use too of melodies which recall to mind any thing, whether in the shape of narrative or sentiment, analogous to what is representing on the stage, is practically found to heighten the effect of the action. But in having recourse to such means great judgment must be shown; for if the composer be not sensible and experienced, he runs considerable danger of exciting ideas very foreign to those which he intended to raise.

To the ancients, what we call the pantomime-ballet was well known. The Rev. Robert Nares, author of 'Remarks on the Ballet of Cupid and Psyche,' says, speaking of what he calls the dance, meaning the mimetic part of it, "Being in its origin used in the service of religion, it thereby acquired a dignity which in modern times it never possessed. The most sacred mysteries of heathenism were thus accompanied. Apollo, in a passage of Pindar, is called the Dancer (ὀρχηστὴς); and there is a Greek line extant which represents Jupiter himself in the very act of dancing. Even at Rome, where the dance was on the whole much less respected, the priests of Mars, to whom the care of the sacred *ancilia* was committed, were, from their customary and solemn dances, denominated *Salii* (from *salio*). Of the imitative dance, both Plato and Xenophon, in the person of their master, Socrates, speak very favourably; and Aristotle ranks it with the art of poetry. Plutarch, in the last book of 'Symposiac Questions,' considered it worthy of distinct discussion. And Lucian, an author certainly not deficient in genius or sagacity, has left an express eulogium, in which he scruples not to prefer the *orchestic* to the speaking dramas. 'The Greeks,' says Athenæus, 'had brought their dance to such perfection, in the art of imitating the passions, that the most eminent sculptors thought their time not ill-employed in studying and designing the attitudes of the public dancers; and to this study (he adds) they owed, undoubtedly, some of the transcendent beauties of their works.'"

The ballet has been essentially a product of the European courts, and a fashionable amusement. In the beginning of the 16th century, Aglio, count of Savoy, himself prepared and acted ballets with the princes and princesses of his court. Baltagerini, the music director of Catherine de' Medici, introduced it into France, where it became so great a favourite that Louis XIII., and even Louis XIV. in his youth, danced in ballets; they were however generally allegorical, and sufficiently tasteless. Quinault first elevated it, and interwove it with some of his operas. In 1697 A. H. de la Motte still further improved it, particularly in its action and dramatic interest. But, appealing almost entirely to the eye, it is continually lowering its character by being forced to adapt itself to the caprices of individual dancers; while for its general effect it depends much on a lavish adornment in scenery, dresses, and decoration. About 1750, however, M. Noverre operated a great change in the ballet, and restored it to nearly the dignity, considered as a public amusement, which it supported among the ancients. We have already quoted his opinions on the ballet, and he very successfully applied them in his productions. His 'Médée,' his 'Déserteur,' and his 'Psyché,' still preserve a high reputation. The influence of these works lasted many years; but at length fashion, almost always opposed to good sense and good taste, would view with favouring eyes nothing but that which passes under the name of dancing; and what ought to be the ballet, is too frequently reduced to a divertissement in which even good grouping is generally neglected. Some successful efforts have however been made in recent years to improve the character of the ballet, and the introduction of the national ballets of other countries has assisted in effecting this. Still, there is too much of mere conventionality, and too much sacrifice of grace, sentiment, and the development of feeling, to exhibitions of mere agility and *tours de force*, often more surprising than pleasing.

BALLISTIC PENDULUM, a heavy wooden pendulum, in section like a gardener's spade: the lower part consisting of a heavy cubical block of wood, plated with iron at the back. It was invented and used by Mr. Robins, the celebrated writer on gunnery, for the purpose of measuring the velocity of cannon-balls and musket-balls. It must be of such a weight that the ball fired into it may not cause a vibration of very great extent. It is described at great length in Robins's 'Principles of Gunnery (we recommend Hutton's edition, London, 1805), prop. viii., and in Hutton's 'Mathematical Tracts,' vol. ii. tract. 34. Those who attempt any experiments with such an instrument should particularly attend to the cautions given by Mr. Robins, who learnt them at the risk of his life.

The principle is as follows:—The pendulum in its state of rest all but touches with its lower end a horizontal bar. To the lower end of the pendulum is attached a ribbon, which passes through an orifice in the bar, moving almost freely. When, therefore, the pendulum is raised, a quantity of ribbon is drawn out, which, if the radius be the whole length of the pendulum, is the chord of the angle through which the pendulum is inclined by the shock. When a shot is fired into the pendulum, no more ribbon is disengaged, during the oscillations which follow, than was drawn out by the first rise of the pendulum; because friction and the resistance of the air will continually diminish the extent of the oscillation. The extent of the first oscillation is greater or less, according as the momentum of the shot is greater or less; and the mechanical problem to be solved is as follows:—Given the weight of the shot, the place at which it strikes, the weight, form, &c., of the pendulum, and the effect produced upon it by the shot; required the velocity of the shot. The formula which answers this question is as follows:

b is the weight of the ball.
p that of the whole pendulum.
g distance from the pivot of the centre of gravity of the whole (after the ball).
i distance from the pivot to the point struck.
c length of ribbon disengaged.
r distance from the pivot to the ribbon.
n the number of vibrations in a minute after receiving the shot.

b and p must be measured in the same unit of weight, and g, i, c, r, in the same unit of length. Then will the velocity of the ball at the moment of striking, *in feet*, be

$$614{\cdot}58\, g\, c \times \frac{p+b}{b\, i\, r\, n}$$

The value of g may be determined by mechanical methods (GRAVITY, CENTRE OF): but if it be determined, as usual, before the shot, then the value of g after the shot is

$$g + \frac{i-g}{p} \times b$$

The ballistic pendulum, in the hands of Robins and Hutton, was useful in supplying information respecting the velocity of cannon-balls, and the resistance of the air to rapid motions. [AERO-DYNAMICS.] It has also tested the correctness of the theory propounded on that subject by Robins. [GUNNERY.] We give in the following table the results of that set of experiments, in which the greatest difference was found between the prediction from theory and the experiment, omitting all the circumstances of each charge, as no connection can be traced between them and the discordances. In the fourth and fifth examples, the barrel had previously lain by in a moist place. Considering the very great difficulty and uncertainty of the subject, the accordance is remarkable. The first two columns represent the length of ribbon disengaged (in inches and tenths), the first from experiment, the second from theory; the third is the difference between the two:

Experiment.	Theory.	Difference.
17·1	17·2	+ ·1
15·2	15·0	— ·2
15·4	15·0	— ·4
11·5	12·8	+ 1·3
11·5	12·8	+ 1·3
8·7	9·0	+ ·3
12·3	12·5	+ ·2
14·4	14·4	0·0
14·4	14·4	0·0
10·3	10·5	+ ·2
14·7	14·5	— ·2
15·7	15·3	— ·4
	Average discordance	+ ·18

When a heavier pendulum was used, the discordances were considerably less. The friction of the pivots was not taken into account in the theory.

It has been proposed to make the gun itself a pendulum, by hanging it as such, and observing by means of a ribbon, the arc of recoil. This instrument was also used by Robins as an *éprouvette* for gunpowder, by firing the same gun with successive charges of powder of different qualities, and using no ball. By first measuring the recoil without the ball and afterwards with it, it is presumed that the additional momentum given to the gun in one direction is also that given to the ball in the other. This there appears no reason to dispute; but the comparison between the gun-pendulum and the ballistic-pendulum cannot be very satisfactorily made, because between the two comes another unknown quantity, namely, the effect of the air on the ball between the instant of leaving the gun and striking the pendulum. But various circumstances, particularly described by Dr. Hutton in the tract alluded to, render the principle assumed in the use of the gun-pendulum very doubtful.

BA'LLIUM; BAILLIE, or BAILEY. This term, according to Dufresne, anciently meant an outer bulwark; but was afterwards adopted for the area or court-yard contained within one. It appears clear from the word, and its original use, that it is a corrupted form of the Latin *Vallum*.

Grose ('Antiq. of Engl. and Wales,' vol. i. pref. p. 7) says, the ditch of a royal castle was sometimes called the Ditch del Bayle, or of the Ballium, to distinguish it from the ditches of the interior works. Over it was either a standing or draw bridge, leading to the ballium. Within the ditch were the walls of the ballium, or outworks. In towns, the appellation of ballium was given to a work fenced with palisades, and sometimes masonry, covering the suburbs; but in castles it was the space immediately within the outer wall. When there was a double enclosure of walls, the areas next each wall were styled the *outer* and *inner* ballia. The manner in which these are mentioned by Camden, from the Chronicle of Dunstaple, in the siege of Bedford Castle, A.D. 1224, sufficiently justifies this position. The castle was taken by four assaults. In the first was taken the barbacan; in the second, the outer ballia; in the third, the wall by the old tower was thrown down by the miners, when with great danger they possessed themselves of the inner ballia through a chink; at the fourth assault the miners set fire to the tower, so that the smoke burst out, and the tower itself was cloven, so as to show visibly some broad chinks, whereupon the enemy surrendered.

The wall of the ballium in castles was commonly high, flanked with towers, and had a parapet, embattled, crenellated, or garretted, for the mounting of it. There were flights of steps at convenient distances, and the parapet often had the merlons pierced with long chinks, ending in round holes, called oillets.

Within the outer ballium were the lodgings and barracks for the garrison and artificers, the stable, hospital, wells, chapel, and even sometimes a monastery. Large mounts were also thrown up in this place: these served, like modern cavaliers, to command the adjacent country; these last being generally raised within the body of the place, ten or twelve feet higher than the rest of the works, and commonly within the bastion. In the inner ballium was placed the keep and the residence of the lord of the castle.

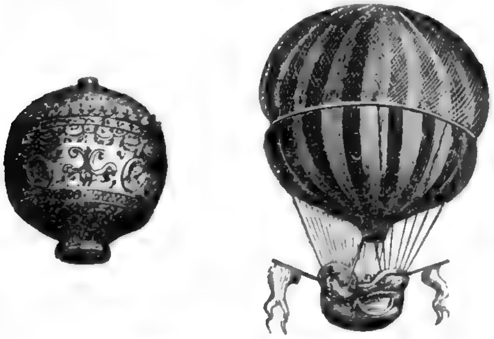
The entrance into the ballium was commonly through a strong machicolated and embattled gate, between two towers, secured by a herse or portcullis. Over this gate were rooms, originally intended for the porter of the castle; the towers served for the *corps de garde*. [CASTLE.]

The church of St. Peter in the Bailey, at Oxford, derives its appellation from having formerly stood within the outer ballium of Oxford Castle. The Old Bailey, or outer space near Ludgate, in London, received its name from its relative position in regard of the ancient wall of the city.

Froissart, in his account of the siege of Amand by the Earl of Hainault, temp. Edward III., says, the attack was so furious that the *baillies* were instantly won. Johnes, in his English 'Froissart' (4to. edit. vol. i. p. 161), translates this word barriers.

(Besides Grose's work already referred to, see Dufresne's *Glossar. ad Script. med. et inf. Ætatis.* fol. Francof. 1681, tom. i. c. 447; King's *Observ. on Anc. Castles*, Archæol. vol. vi. pp. 249, 308; *Munim. Antiqua*, vol. ii. p. 45; Ellis's *Fableaux*, edit. 1815, vol. i. p. 153, Notes; De Caumont, *Architectures Civile et Militaire*, &c.)

BALLOON, from the French *ballon*, a little ball, is a word applied, in our language, only to the well-known machine which, consisting of an envelope of silk or other stuff filled with hydrogen or other gas specifically lighter than the atmosphere, is employed to raise those who trust themselves to the chances of a safe voyage in the air. It is scarcely correct to dignify the exploits of ballooning with the title of *Aëronautics*, sometimes applied to them; for our air navigation, compared with that of the sea, is little more than on a level with the essay of the first rude men who discovered that a hollow wooden vessel might be made large enough to float a body heavier than water. The first step towards guiding the machine is yet to be made; and some little power of ascending and descending is all that has been gained. Nevertheless, the subject is an interesting one, and must briefly be traced here.



Montgolfier's first and second Balloons.

The notion of imitating the flying of birds is very ancient. We pass over the winged gods, the stories of Abaris, Dædalus, and the like, as fictions which, like many others, might have been purely imaginative, and not traditions of any previous reality. But Strabo (p. 296) mentions the Capnobatæ (or Capnioi, as has been conjectured), a Scythian people, who (so the word has been very foolishly interpreted) raised themselves by smoke, as the vulgar first imagined Montgolfier did. The Carolinians are also mentioned by the Jesuit Cantova as having a fable about a female deity who raised herself to heaven by the smoke of a great fire. We may also mention the pigeon of Archytas, the oracle of Hierapolis, which Lucian professes to have seen raise itself in the air; the fable, in British mythology, of Bladud or Baldud, the father of the well-known Lear, which resembles that of Dædalus; and many others, all of which serve to show that the notion of the possibility of raising a man or a machine was very widely extended in the ancient world. Roger Bacon ('De Mirabili Potestate,' &c.) says that there certainly is a flying machine, of which he knows the name of the inventor, but which he has neither seen himself, nor any one whom he knows. Van Helmont and others proved the possibility of flying, by very eloquent discourses, which convinced all hearers. Bishop Wilkins, in his 'Mathematical Magic,' 1680, proposes a carriage, with sails like those of a windmill, to be driven by the air; and the same thing, according to custom in the case of all inventions, has been attributed to the Chinese. We shall only mention Schott, Baptista Porta, Cardan, and Fabri, as having maintained the possibility of flying. The Jesuit Francis Lana (1670), among many other projects, has given perhaps the first idea of a real balloon, as we have defined it. He proposes to raise a vessel by means of metal balls, strong enough, when exhausted, to resist the pressure of the external air, but at the same time so thin as, in the same circumstances, to be lighter than their bulk of air. To the possibility of this he asserts that he sees no objection, except that the Almighty would never allow an invention to succeed, by means of which civil government could so easily be disturbed. A reason of this sort was all powerful in his age, which abounded in a pretended knowledge of the minutest secrets of Providence: had the good father tried the experiment, he would have found that strength to resist the external air is incompatible with the necessary degree of thinness in the material, as was observed by Leibnitz.

In the 'Ars Magnetica' of Kircher, that author describes a method of imitating the dove of Archytas, by attaching the bird by a string to the hand of a statue, over which is a large dial; a magnet revolving behind the dial would cause the dove to fly round the head of the statue, and point to the hour of the day. The oft-told story of Regiomontanus constructing an eagle which flew out from Nürnberg to meet the Emperor Charles V., and on meeting him flew back again over his head to the town, is refuted by the simple fact that Regiomontanus died twenty-five years before Charles V. was born. Although the art of flying had been diligently studied, or at least discussed, for centuries, the exceedingly simple contrivance of Montgolfier had not been tried, or even mentioned, by any of the projectors, some of whom were men of ingenuity. We consider him the inventor of the balloon who raised a mass of solid substance to some considerable height in the atmosphere. But if we were to take the licence which is so common, of disputing the right of an inventor on account of some previous experiments containing a principle common with his own, we might either say that this machine has been invented from time immemorial, in the ascent of soap-bubbles; or we might cite Candido Buono, who made one scale of a balance ascend, by rarefying with a red-hot iron the air underneath it. After Cavendish had ascertained how much hydrogen weighs less than air, it immediately occurred to Dr. Black, that a light substance, filled with the above-mentioned gas, would rise of itself. But he did not pursue the idea farther; and Cavallo, who tried to put it in practice in the year 1782, could not succeed in raising, by means of hydrogen, anything heavier than a soap-bubble. We shall see that, natural as it might appear to use hydrogen for the purpose, the experiment succeeded only with a very different agent.

Stephen and Joseph de Montgolfier were paper-manufacturers at Annonay, not far from Lyon. They had both studied natural philosophy and chemistry, and their business gave them facilities for procuring large masses of light envelopes: so that we owe the invention of balloons to one of two accidents—either to that of philosophers being paper-makers, or to that of paper-makers being philosophers. Struck with the notion of confining something lighter than air in a recipient, as the means of making the latter ascend, they tried this method at about the same period as M. Cavallo, by confining hydrogen in paper. They succeeded to some extent; but the gas so soon escaped through the paper, that they abandoned the idea of anything like permanent elevation by means of it. The next thought which struck them was, that as it was supposed the elevation of the clouds was caused by the presence of electric matter, and as it seemed to them from some experiments that electrified bodies were diminished in weight, it might be possible to raise a surface, of great extent in proportion to its specific gravity, by means of electricity. After trying various methods, they applied fire underneath a balloon, not to rarefy the inclosed air, but "as well to increase the layer (*couche*) of electric fluid upon the vapour in the vessel, as to divide the vapours into smaller molecules, and dilate the gas in which they are suspended." The experiment succeeded; and a balloon of 23,000 cubic feet (French) capacity was raised with considerable force. All this took place early in 1782; and at that time the electric theory was stated as above. But in the report made to the Academy of Sciences (December, 1783) by the commission appointed to examine Montgolfier's invention, the inventors are spoken of as simply rarefying the air contained in the balloon; probably by that time further consideration had led them to the correct view of the subject. J. Montgolfier, in his memoir, says, "Large balloons might be employed for victualling a besieged town, for raising wrecked vessels, perhaps even for voyages, and certainly, in particular cases, for observations of different kinds; for reconnoitring the position of an army, or the course of vessels, at twenty-five or even thirty leagues distant," &c. One of these ideas was put in practice at the battle of Fleurus, where the French made a reconnoissance and prevented a surprise by means of a balloon.

The first public experiment was made at Annonay, June 5, 1783. At the appointed time, nothing was seen in the public place of the town but immense folds of paper 110 feet in circumference, fixed to a frame, the whole weighing about 500 pounds, and containing 22,000 cubic feet (French measure). To the great astonishment of all, it was announced that this balloon would be filled with gas, and would rise to the clouds, which very few could believe. On the application of fire underneath, the mass gradually unfolded and assumed the form of a large globe, striving at the same time to burst from the arms which held it. At length it rose with great rapidity, and in less than ten minutes was at 1000 toises (6000 French feet) of elevation. It then described a horizontal line of 7200 feet, and gradually sank. This balloon contained nothing but heated air, maintained in a state of rarefaction by a fire, the receptacle of which was attached underneath the globe of paper, which had an orifice opening downwards. Machines on this principle were called *Montgolfiers*, to distinguish them from the hydrogen balloons, which were soon afterwards introduced. It was immediately resolved to repeat the experiment with hydrogen inclosed in lutestring, which had been dipped in the solution of Indian rubber. A subscription was opened, and the balloon was ready for filling on the 23rd of August. The gas was obtained in the usual manner, by the action of dilute sulphuric acid on iron filings. But the difficulty of filling the machine was very considerable; and it was not till after two or three trials that success was attained. The first aërial voyagers were a sheep, a cock, and a duck, who were sent up in Montgolfier's experiment of the 19th of September, in the same year, at Paris. All came down safe with the exception of the second, whose wing was hurt. It was judged prudent not to trust human life to a free balloon till the experiment of holding the machine with ropes had been tried. In this manner M. Pilâtre de Rozier ascended 100 feet on the 15th of October, and 324 feet on the 19th. The first persons who offered to leave the earth entirely were the Marquis d'Arlandes and M. Pilâtre de Rozier; and they performed this feat at the Château de la Muette, near Passy, November 21, 1783, in a *Montgolfier*. Of this most interesting of all balloon ascents, the 'Procès Verbal' gave the following account: "To day, November 21, 1783, at the Château de la Muette, took place an experiment with the aërostatic machine of M. de Montgolfier. The sky was partly clouded, wind north-west. At eight minutes after noon, a mortar gave notice that the machine was about to be filled. In eight minutes, notwithstanding the wind, it was ready to set off, the Marquis d'Arlandes and M. Pilâtre de Rozier being in the car. It was at first intended to retain the machine a while with ropes, to judge what weight it would bear, and see that all was right. But the wind prevented it from rising vertically, and directed it towards one of the garden walks; the ropes made several rents in it, one of six feet long. It was brought down again, and in two hours was set right. Having been filled again, it set off at fifty-four minutes past one, carrying the same persons. It rose in the most majestic manner, and when it was about 270 feet high, the intrepid voyagers took off their hats and saluted the spectators. No one could help feeling a mingled sentiment of fear and admiration. The voyagers were soon undistinguishable, but the machine, hovering upon the horizon, and displaying the most beautiful figure, rose at least 3000 feet high, and remained visible all the time. It crossed the Seine below the barrier of La Conférence; and passing thence between the Ecole Militaire and the Hôtel des Invalides, was in view of all Paris. The voyagers, satisfied with their experiment, and not wishing to travel farther, agreed to descend; but seeing that the wind was carrying them upon the houses of the Rue de Sève, Faub. St. Germain, they preserved their presence of mind, increased the fire, and continued their course through the air till they had crossed Paris. They then descended quietly on the plain, beyond the new boulevard, opposite the mill of Croulebarbe, without having felt the slightest inconvenience, and having in the car two-thirds of their fuel. They could then, if they had wished, have gone three times as far as they did go, which was 5000 toises, done in from 20 to 25 minutes. The machine was 70 feet high, 46 feet in diameter; it contained 60,000 cubic feet, and carried a weight of from 1600 to 1700 pounds." The Marquis d'Arlandes wrote a lively and instructive account of the ascent, in a letter to M. de St. Fond; but it is too long to be given here.

The second voyage was that of MM. Charles and Robert, Dec. 1, 1783, from the Tuileries, in a hydrogen balloon of 26 feet diameter,—all experiments on the use of hydrogen for the purpose having previously been on a very limited scale. After coming down, M. Charles re-ascended alone, and was soon 1500 toises high, or nearly two miles. A small balloon, launched by Montgolfier just before the ascent, was found to have run a totally different course, which first gave rise to the suspicion of different directions in the currents of air at different heights.

The third voyage, from Lyon, January 19, 1784, was made in the largest *Montgolfier* yet constructed (102 feet diameter, 126 feet high) by seven persons, among whom were J. Montgolfier and M. de Rozier. It had been intended for six only, and these were found too many, but no persuasion could induce any one to abandon his place. The instant after the ropes had been cut, a seventh person jumped in. A rent in the balloon caused it to descend with perilous velocity, but no one was hurt.

This amount of success led to great activity in ballooning. Shortly before the ascent of MM. Charles and Robert, a hydrogen balloon was launched in London by Count Zambeccari. In 1784 a small balloon was sent across the English Channel, travelling from Sandwich to Lisle at the rate of 30 miles an hour. In the same year, M. Blanchard ascended from Paris with a balloon provided with wings, a rudder, and a parachute; the wings and rudder were found to be useless; but the parachute, opening like an umbrella, tended to break the velocity of the descent. About the same time, MM. de Morveau and Bertrand ascended 13,000 feet at Dijon, in a balloon provided experimentally with oars. On one occasion, in 1784, two gentlemen and four ladies accompanied Montgolfier in a 'captive' balloon, held in position by ropes; and on another occasion a lady ascended at Lyon with an aëronaut in a free balloon. Before the end of that year, Lunardi ascended in a balloon from London. In 1785 Blanchard and Jeffries crossed the English Channel in a balloon, narrowly escaping precipitation in the sea. In the same year, MM. Pilâtre de Rozier and Romain ascended from Boulogne in a *Montgolfier* of 37 feet in diameter, with the intention of crossing the Channel. They had not been twenty minutes in the air when the balloon took fire. Both fell from a height of 1000 yards, and were killed on the spot. In 1802 General Money ascended at Norwich; the balloon dropped into the water, in which the traveller remained six hours before he was rescued. In the same year M. Garnerin descended successfully from a balloon by means of a parachute, near the Small-pox Hospital, St. Pancras, London. The height from which he descended was so great that he could scarcely be distinguished. At first—namely, before the parachute opened—he fell with a great velocity; but as soon as it was expanded, the descent became very gentle and gradual. In 1804, Messrs. Gay Lussac and Biot ascended at Paris to a height of 13,000 feet, provided with apparatus for making certain scientific experiments. The same year M. Gay Lussac ascended alone to a height of 23,000 feet. In 1806, Carlo Brioschi, astronomer royal at Naples, ascended with Signor Andreani, who had previously been the first Italian aëronaut. Trying to rise higher than M. Gay Lussac had done, they got into an atmosphere so rarefied as to burst the balloon. Its remnants checked the velocity of their descent; and this, with their falling on an open space, saved their lives, but Brioschi contracted a complaint which brought him to his grave.

It would be neither possible nor useful to trace the records of balloon ascents in any detail; but a few notices of the course of experiments during the last half century may be desirable.

Although much has been suggested, scarcely anything has been accomplished towards rendering balloons available for any practical use. Little has been done towards guiding a balloon. Many of the schemes which have been proposed for the purpose, evince a singular disregard of the essential difference between a ship and a balloon. The former sails in two fluids of very different density; and the action of the water, the denser of the two, upon the rudder, is a guide to the impelling power derived from the air or lighter or less dense element; but no such regulator can be applied to the balloon, which is sustained, as well as impelled, by the air.

Mr. Green has been the most successful of our aëronauts. He was the first to introduce the use of common coal gas instead of hydrogen gas for the purpose of inflation, by which an immense saving of cost is effected, and the buoyancy of the balloon may be longer maintained, as coal gas is far less liable to escape than hydrogen. Mr. Green, accompanied by Messrs. Holland and Monck Mason, made the remarkable voyage undertaken on the 7th of November 1836, with the Great Nassau balloon. Intending to cross over to the Continent, these voyagers started from Vauxhall Gardens, London, at half-past one on the above-named day, crossed the Channel, continued their voyage through the night, and descended at half-past seven the following morning in the valley of Elbern, about two leagues from Weilburg, in the duchy of Nassau. The balloon with which this feat was performed was of silk, more than 60 feet high, and about 50 feet in diameter, and contained, when fully distended, more than 85,000 cubic feet of gas.

Much ingenuity continues to be unprofitably wasted on ballooning. Year after year contrivances are brought forward which have before been shown to be unsound in theory. In 1840 Messrs. Marsh and Ranwell suggested a complicated machine, consisting of a light metallic frame, to which about twenty small balloons were attached. Sir George Cayley proposed a light kind of frame, exposing about 500 square feet of surface, to which some sort of steering apparatus was to be attached. Mr. Partridge has drawn attention to a machine which had somewhat the appearance of an ovoid balloon, with a complicated apparatus of sails and vanes, and a steam-engine fed with liquid fuel! M. Eubriot, in 1839, made an oblong balloon, with a car provided with sails. He expected that the car and sails would guide the balloon; but when the machine was tried at Paris, the balloon guided the car, as it is the wont of balloons to do. Mr. Green himself, in 1840, exhibited a model at the Polytechnic Institution, of an apparatus which he expected would suffice to guide a balloon, but nothing satisfactory resulted. About that same year, Dr. Polli, of Milan, suggested that the structure of a fish should form a model for an aërial locomotive; but he was forestalled in this obvious but fallacious idea by other parties in England. In 1842, Mr. Henson took out his patent for that "aërial machine" which lived its little day of popularity, and then went out of sight. A small steam-engine, in a car, was to propel a light framework 150 feet long; and a tail 50 feet long was to serve as a rudder at one end; but whether the machine could raise itself to a height, or could propel itself by the engine, or could steer itself by the tail, were inquiries never satisfactorily answered. Next came M. Monge's copper balloon, constructed at Paris in 1844; it was about 30 feet diameter, formed of sheet copper $\frac{1}{80}$th of an inch thick, weighed 800 lbs., and was capable of containing 100 lbs. of hydrogen. The egg-shape, the fish-shape, the fan-shape, the kite-shape, all have been proposed, time after time. Mr. Bell patented two machines—a *balloon motor*, having both a sustaining and a propelling power; and a *parachute motor*, having a propelling power which constituted its own sustaining power. The plan looked ingenious upon paper, but this is not very high praise.

Occasionally balloons have been made subsidiary to science, but very seldom. The British Association has more than once directed its attention to this matter, but with very little result. In 1843, Mr. Green made observations with meteorological instruments at five different elevations, varying from 2591 to 6758 feet; while Mr. Jones, the instrument maker, was making similar observations at the surface of the earth at the same time; such observations as these might perhaps be multiplied with advantage. Mr. Rush communicated to the British Association, in 1849, a series of thermometrical and barometrical observations, made during five balloon ascents, in 1847-8-9, at various altitudes ranging up to 20,000 feet.

A suggestion was made about the year 1851, for sending out balloons to assist in the search for Sir John Franklin; and in 1854 balloons were suggested for reconnoitring Sebastopol.

The last seven years (1852 to 1859) have shown that the hope is not yet quite extinguished among ingenious, but not very profound, machinists, of being able to guide balloons through the air. In 1852 Mr. Graham added to the list of contrivances intended to aid in the steering of balloons, by means of levers, sails, rudders, &c. In 1856 another inventor brought into notice an "Archimedian balloon," comprising a great variety of mechanical appliances, including a wooden framework, four paddle-wheels, some new kind of chemical engine to supply moving power, and a screw propeller. The inventor's hope was, that the turning of the screw would bring the balloon into any desired direction, and that the paddles would give progressive motion. The balloon was a cylinder, with hemispherical ends, placed immediately over the hull of this aërial screw-ship. The project never appears to have gone beyond the condition of a model. Dr. Lotszky, in the same year, proposed a suite of small balloons and wings, to be attached to "a slim youth," as a means of enabling him to fly over the Crystal Palace grounds. The latest enthusiast is Lord Carlingford, who in 1857 brought into notice his "Archedon," or aërial chariot. It had before been shown in model at the Dublin Exhibition; but as it obtained few admirers, the inventor afterwards made sundry improvements in it. It consists of a sort of light boat, with one wheel in front and two behind; there are two concave wings at the sides, held up by laths, cords, and hoops; and there is a tail, which can be raised or lowered at pleasure. The moving power is a winch turned by the aëronaut; the winch acts through a train of multiplying wheels, upon an Archimedian screw; this screw acts upon the cords which move the sails. The wings are covered with network and silk. It is not often that the specification of a patent contains such glowing language as that which Lord Carlingford used in reference to his invention: "Like the chariot of Jupiter, we may yet behold the eagle trained to draw the aërial chariot." In a letter to the 'Mechanics' Magazine,' his lordship thus commented on the mode in which his invention was received: "The first chariot I made was placed in the Dublin Exhibition; yet, strange to say, although clear and simple as was the principle of it, it was not understood, nor even examined, but left in such an obscure position, that no doubt it was concluded to be some nonsensical production; yet none were courageous enough to question the principle, or to approve it, though challenged to do so."

Of all these contrivances, it may simply be said that the means of guiding balloons through the air have yet to be discovered; that the higher the scientific attainments of the aëronaut, the less sanguine is he of any such means ever being devised. Balloons may possibly, some day, render more service to meteorology than they have yet done, by testing currents, &c., high up in the atmosphere; and indeed the British Association, in 1858, made a grant of money for further experiments in this direction.

BALLOT, a word taken from the French *balotte* or *ballotte*, signifying a little ball, and used to designate a mode of voting employed upon occasions where it is considered desirable to preserve secrecy in regard to the opinion of each voter. In many cases where any matter is decided by votes, there are good reasons why it should be generally known how each person has voted; but there are other cases in which there may be equally good reasons for allowing the voters to vote by ballot. Voting by ballot, therefore, cannot be called either a good or a bad system of voting, without considering the particular cases in which it is exercised.

In Great Britain it has been agitated for many years whether the election of members of Parliament should or should not be by ballot. It is a question we are not called on to decide, and much has been written and said on both sides. It may be remarked, however, that there is no strict analogy between the election of members of a private society, or even of a public association, and of members elected for political and legislative purposes. In the one, private reasons which could not be openly stated with propriety, may, and ought to, operate against the admission of an individual as an associate; while, in the other, as it is his public character that should give him the necessary qualification, there is the less reason for secrecy. His public defects, if any, should be publicly stated, to enable him to meet them; he is a representative, and ought not to be rejected on grounds that cannot be publicly stated. Again, as it is said that martyrs make a faith, it is not impossible that the ballot, by ensuring secrecy, may also create indifference, when the public mind is no longer stirred up by the excitement given by open voting; although that may too frequently lead to instances of oppression and hardship suffered in consequence.

The modes of performing the voting by ballot vary, in some respects, according to the object to be attained; as for instance, in the case of an election to an office where the choice can fall upon only one candidate, or upon a smaller number of candidates than are put in nomination, it is usual to deliver lists which are folded so as to conceal the name or names which they bear, and which, in that condition, are placed in a glass or urn, from which, after the votes are all collected, they are taken and examined, in order to determine in whose favour the greatest number of votes has been given. In cases where a simple affirmative or negative is alone required, the same method is sometimes employed, and then the papers deposited in the urn bear only the word 'Yes' or 'No.' Sometimes the original mode of voting by ballot is more strictly adhered to, and balls are used in one of two ways. One of these ways is to choose in which of two compartments into which the urn is divided, the voter will deposit the ball; the other method is to select the colour of the ball to be employed. In cases where the last-mentioned method is resorted to, each voter is furnished with two balls, one white and the other black; the black ball is used to express a negative, whence comes the expression 'to blackball,' signifying the rejection of a candidate. In determining this point of rejection, no uniform rule is observed by different bodies. In some societies or bodies, one ball is made sufficient to negative the election; sometimes a larger number of adverse votes is necessary for this purpose. Other bodies adopt as a regulation some definite proportion between the rejecting and accepting votes, such as one in three, five, ten, &c., whereby to determine upon the admission of the candidate.

This mode of election is now almost universally resorted to in England by clubs and scientific societies, as well as in hospitals for the election of medical officers, and by insurance offices and commercial associations for choosing their managers or directors. The directors of the Bank of England are thus chosen.

In France, voting by ballot is used in the election of members of the Chamber of Deputies, and the same mode of voting was used under the constitutional charter in the chamber itself whenever twenty members concurred in demanding a ballot; but in 1845, the practice was abolished by a law proposed by M. Duvergier de Hauranne, during M. Guizot's administration. The most remarkable instances, however, of the exercise of the ballot, are those of the election of Louis Napoleon to the office of president; and the ratification by the same process of the *coup d'état* of December, 1851, and the consequent elevation of the president to the throne of the empire.

M. de Tocqueville, though he discusses the constitution of the United States in all its phases, does not think the ballot of sufficient importance to give it even a notice as having any effect, while he dwells strongly on the great influence of publicity, and the passion for general and varied political discussion, which he thinks a marked characteristic of the American people as distinguishing them from Europeans.

BALSAM. This name is applied to a class of substances which are exclusively ready formed products of the vegetable kingdom. They are chiefly produced in warm climates, and consist of a mixture of ethereal oils with resinous bodies, frequently containing also benzoic or cinnamic acid, to which their aromatic odour is due. The balsams are of a semifluid or viscous consistence, and are generally obtained by making incisions in the bark of the trees which produce them. By exposure to the air the more volatile part evaporates and they become harder, but it is rarely that they thus entirely lose their viscosity. In addition to these natural productions, some artificial balsams, as balsam of sulphur, are employed in medicine. The following are a few of the principal natural balsams:—

Balsam of Canada. A terebinthinous balsam, obtained from the Balm of Gilead Fir (*Abies balsamea*). It is a transparent honey-like yellowish liquid, becoming hard on exposure to the air. It possesses the odour of turpentine and a bitter taste. Canada Balsam consists of

Essential oil	18·6
Resin soluble in alcohol	40·0
Resin insoluble in alcohol	33·4
Elastic resin	4·0
Bitter extractive and salts	4·0
	100·0

Canada Balsam is used for cementing together the constituent lenses of achromatic combinations.

Balsam of Capivi. This balsam is a resinous exudation from different species of *Copaifera*. It is a clear liquid, which thickens on exposure to the air, and has a specific gravity from ·95 to ·96. It is insoluble in water, but soluble in alcohol, ether, and oils. Alkalies convert it into an insoluble soap. According to Gerber it consists of

	Fresh Balsam.	Old Balsam.
Volatile oil	41·00	31·70
Yellow resin (*Copaivic acid*)	51·38	53·68
Brown soft resin	2·18	11·15
Water and loss	5·44	4·10
	100·00	100·63

Balsam of Peru. Two descriptions of this balsam are met with, both obtained from the same tree, ***Miroxylum Peruiferum*** : one is solid, the other liquid. The first is the true balsamic juice in a concrete state, the last is prepared by boiling the bark of the tree in water. The solid balsam is hard, translucent, and of a light-red colour. It possesses an aromatic odour and taste, due chiefly to the presence of cinnamic acid. The liquid balsam is of a syrupy consistence, reddish-brown and transparent, of a powerful but pleasant odour resembling liquid styrax, and an insupportably bitter taste. It is used in medicine and perfumery, and is often adulterated with alcohol, fixed oils and balsam of capivi.

Balsam of Tolu. The concrete juice of ***Myrospermum Toluiferum***. It is a brownish yellow resinous mass, emitting a fragrant odour. It consists, according to Kopp, of free *cinnamic acid*, a liquid hydrocarbon, *Tolen* ($C_{10}H_8$) and two resins; *Alpha Resin* has the formula $C_{36}H_{18}O_4$, and is brown, translucid, brittle, and shining. *Beta Resin* ($C_{36}H_{20}O_{10}$) is of a dull yellowish-brown colour. It is tasteless and inodorous.

BALSAMODENDRON, *Medical uses of.* Myrrh, some of which is the product of the *Balsamodendron myrrha* and *katof* [NAT. HIST. DIV.], is a gum resin, and is met with of two sorts—myrrh in tears and myrrh in sorts. The smell is peculiar and disagreeable, and the taste is bitter. The myrrha stacte mentioned in Exodus xxx. 34, was esteemed the finest kind of myrrh by the ancients, being the spontaneous exudation from the plant. Myrrh in sorts is coarser and frequently adulterated. The alcoholic tincture of myrrh mixed with equal parts of nitric acid, becomes red or violet. The tincture of the false myrrh (of Bonastre) so treated, becomes turbid and yellow, but not red.

East Indian myrrh is in large pieces, altogether opaque, frequently covered with a brownish-white powder. The source of this is unknown, but it is conjectured by Louriero, that a tree called *Laurus myrrha*, a native of Cochin China, yields it. The so-called myrrh of Abyssinia, which is *gum opocalpasum*, is yielded by the *Acacia gummifera* (Wild.), called also *Inga Sassa*, and is probably a variety of the gum of Bassora or Bagdad.

A portion of myrrh brought from Arabia by Ehrenberg, analysed by Brandes, yielded

Resin, soluble in ether	22
Resin, insoluble in ether	5
Gum	54
Bassorin	9
Volatile oil (myrrh oil), which is heavier than water	2
Traces of salts, malates, benzoates, and sulphates.	

Its specific gravity is 1·360. Water dissolves about 66 parts, one-third of which is deposited upon standing. Alcohol dissolves the remaining 34 parts; but on the addition of water, it becomes opaque and milky, but without any precipitate. Acetic acid and milk also dissolve it.

Myrrh, though containing a volatile oil, seems to act more from its bitter qualities, which approach to the character of a stimulant tonic. It increases the energy of the whole frame, giving solidity to the solids, and greater consistency to the fluids. The secretions of the mucous membranes particularly are improved by it, and diminished in quantity when excessive. Its introduction into the stomach is followed by a sense of warmth, which diffuses itself over the whole abdomen. The appetite is increased, and the digestive process is much facilitated, especially where there is weakness and torpidity of the intestinal canal, sometimes accompanied by too copious mucous secretion (constituting what is termed *diarrhœa mucosa*).

The mucous membrane of the lungs is acted upon in the same way; hence myrrh is very useful in affections of languid and feeble persons, who are unable to expectorate the abundant fluids secreted by the air-tubes (bronchia). For the humid and chronic cough of old people it is very serviceable, especially if given along with sulphate of zinc. For the cure of a cough which often occurs during pregnancy, and even continues after abortion, along with oxide of zinc, it is well-suited; as well as for hysterical coughs, in which last it may be given along with cinchona bark, or preparations of iron.

From its cleansing power in the case of external ulcers, it has been recommended in consumption (*phthisis pulmonalis*); but in the early stages, or even the later, if there be much hectic fever, it is quite inadmissible: and when allowable, it is only useful by imparting strength to expectorate, having no power to cure the disease.

In amenorrhœa occurring in feeble persons, it is of great use, along with aloetic medicines and preparations of iron.

It is best given in substance in the greater number of cases in which it can be employed; but as a means of cleansing ulcers, as well as a wash to parts in danger of ulcerating from pressure (as in patients long confined to bed, from fever, fractured limbs, or other causes), the tincture is preferable.

Myrrh is an ingredient in a great many tooth-powders.

The produce of the *Balsamodendron Gileadense*, though called a balsam, and denominated balsam of Mecca, balsam of Gilead, is not entitled, chemically, to rank as such, being an *oleo-resin*. It is of two kinds, that obtained by spontaneous exudation, and that which is obtained by boiling the branches. The former is so highly prized in the East, and so expensive, that it is never brought to Europe. That which is obtained by boiling is of different qualities and value, according as the boiling is continued for a short or long time. When for a short time only, the substance which floats on the surface is highly esteemed, and almost all of this quality is consumed in Asiatic Turkey and Egypt. The variety procured by long-continued boiling is sent to Europe in small conical, leaden bottles, the mouth of which is closed with a leaden stopper, and covered over with bladder. The fresh balsam is of moderate consistence, of a light yellow colour, odour agreeable, the taste bitterish, aromatic, and heating; specific grav. 0·950. When dropped upon water it spreads out into a thin film, which may be skimmed off the surface with a spoon. When exposed to the air for some days, it loses this property, as well as its fine smell. It has been described by Strabo (b. xvi. p. 763): "The balsam is a shrub of a brambly appearance or kind, like the cytisus and terebinthus, and possesses aromatic properties. They cut the bark, and catch the juice that exudes in vessels; the juice resembles oily milk. When put into shells it hardens, or assumes consistence. It has wonderful powers in curing headaches, incipient defluxions (he means catarrhs), and dimness of the eyes: it is accordingly high-priced. The xylobalsamum is also used as an aromatic."

Numerous fabulous statements are recorded in writers on medical substances respecting this article: such, for example, as the mode of judging of its purity by dipping the finger in it, and then setting fire to it, when, if it burns without causing pain, it is considered pure. From its high price it is often adulterated with sesamum oil, the produce of the ***Pinus balsamea*** and ***P. Canadensis***, Chian turpentine, and even tar. A portion of the purest kind, analysed by Trommsdorff, yielded

Volatile oil	30 per cent.
Resin (with some extractive)	64 „
Resin, insoluble in alcohol, a small quantity.	

It burns without leaving any residuum.

Though formerly considered a cure for many diseases, it has now fallen into disuse. Any benefit which might be derived from it can be obtained from any of the finer turpentines. Its heating qualities render it very unfit for cases where any inflammatory action exists, whether internal, as consumption, or external, as wounds. There is reason to believe that many of the cordials sold under the name of balms contain no portion of Mecca balsam; but that the most celebrated of these medicines, called Solomon's Balm of Gilead, consists of cardamums and brandy, which must be even more hurtful than any balsam.

BALSAMS. The substances commonly included under this title are of various natures: first, there are natural balsams, exuding from trees, as those of Peru and Tolu, &c., which contain benzoic acid and resin, and these only will be considered at present. There are, besides, the balsams of Copaiba, Gilead, &c.; these contain no benzoic acid, but are turpentines containing a volatile oil and resin; these will be described as turpentines. Lastly, there were in former pharmacopœias sundry very different preparations ranked together as balsams. For example, balsam of sulphur, traumatic balsam, &c.: these, when retained in modern pharmacopœias, are arranged under other forms.

Balsams are obtained from certain vegetables, chiefly of the *Leguminosæ* or pea tribe, the *Styraceæ* or storax tribe, and that section of *Amentaceæ* called *Salicineæ*. Numerous substances of a resinous nature were formerly designated *balsams*, and turpentines and balsams are still popularly confounded with each other. The term balsam, however, should be limited to such articles as contain *benzoic acid* along with a volatile oil and resin. The others, which contain only volatile oil and resin, should be called turpentines, or oleo-resins. The true balsams appear to be only five, namely, balsam of Peru and balsam of Tolu (yielded by the ***Myrospermum Peruiferum*** and ***M. Toluiferum Leguminosæ***), and benzoin, from *Styrax benzoin* (*Dryander*), and storax, from *Styrax officinalis* (*Styraceæ*), and liquidamber, from the *Liquidambar Styraciflua* and *L. imberbis* (*Salicineæ*).

The observations upon the medical uses of balsams are therefore to be understood to apply only to those specified above. To produce their characteristic effects, they must be digested and assimilated, on which account they are chiefly administered internally, their external application being followed by very limited action. They are with difficulty soluble in the animal juices, so that it is not till after they have been used for some time that the secretions acquire their peculiar odour. These facts, taken into consideration along with the enduring nature of their action, point out their greater fitness for chronic than acute diseases.

They may be regarded as stimulants of the secretory and excretory systems, which they rouse to continued action. Their influence is greatest over mucous membranes, the secretions from which they render more abundant when deficient, and more consistent when too liquid and of imperfect quality. The mucous membranes of the lungs and of the urinary passages seem to be more under their influence than that of the intestinal canal. They possess a similar power over the skin, the secretion of which they regulate according to its condition: when cool, pale, dry, and in a state of atony, they promote the perspiration; but if the weakness be so great that the skin is covered with a cold, clammy sweat, or of a colliquative kind, the balsamic medicines frequently check its flow.

When given in large and long-continued doses, they act upon the vascular system, and quicken the heart's action, as well as the extreme or capillary vessels, which last they excite when brought into direct contact with them, as in the case of wounds or ulcers.

They possess some power over the nervous system, but less over the nerves of animal than of organic life. It is in diseases referable to morbid states of the nerves of organic life that balsamic medicines are most useful, especially when they are in a state of weakness, torpor, and imperfect action. They act also on the nervous system when over-excited, calming it, and approaching in this respect to the character of antispasmodics. Under this head benzoin is the most powerful and most frequently employed, generally in the form called *paregoric elixir*.

From what is stated above, it is clear that they are unsuited to the beginning or early stages of the diseases in which they are most commonly employed by uninformed persons. So long as any acute inflammatory action exists they are decidedly hurtful; but after this has subsided they are frequently very beneficial in common colds, to lessen the cough and facilitate the expectoration, in the later stages of hooping-cough, and in the humid cough of old or weak persons; that is, in one of the morbid states popularly called asthma. Balsamic medicines are however totally inadmissible when the asthmatic symptoms are connected with any organic change of the heart or lungs. They may be advantageously employed in the later stages of influenza and suffocative catarrh. The early use of paregoric in common colds is frequently productive of much injury.

The external employment of balsams is almost completely banished from modern surgery. The evil of their employment was obvious to the eyes. *Friar's balsam, wound balsam, balsam for cuts, &c.*, as certain combinations or solutions of balsam of Tolu, storax, and benzoin in rectified spirits were called, had, when applied to recent wounds, the manifest bad effect of stimulating the edges, and interposing a mechanical impediment to their union by *the first intention*, as the direct re-union of divided surfaces is termed by surgeons. In this way they were healed by suppuration and granulation, which is a much more tedious process. To some indolent wounds and sores, especially in parts not possessed of much vascularity, their application is sometimes beneficial. Internal wounds and ulcers are in general equally injured by them. Their vaunted power of curing consumption is only maintained by ignorant and unprincipled persons, who vend their pernicious compounds to the weak and credulous among their suffering fellow-creatures, whom they delude both of health and money.

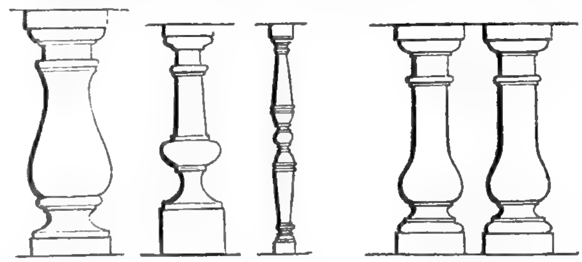
[For balsam of Canada, see PINUS BALSAMEA; for balsam of Copaiba, see COPAIFERA; and for balsams of Peru and Tolu, see MYROSPERMUM in NAT. HIST. DIV.]

BALUSTER, or BALLISTER, has been derived from balustrum, or balustrium, a place railed off in the ancient baths. (Nicholson's 'Architectural Dictionary.') It is also conjectured to be derived from 'balaustium' (βαλαύστιον), the flower of the wild pomegranate, which it is said to resemble. ('Encyclopédie Méthodique d'Architecture.') It is difficult to imagine how the word 'baluster' is derived from the Greek name of the flower of the pomegranate, when we do not even know the form of the ancient baluster, or whether it bore any resemblance to that of the moderns. We think it more probable that the word was derived from balista, an engine used by the Romans for throwing stones, &c. (Vitruvius.) Balista was the engine, and balistarium the place where the balista was put; and it is possible the balistarium was railed in. The balistarium was, according to Lipsius, the engine itself. (Plautus, 'Pœnul.', i. 1, 73; Lipsius, 'Poliorcet.' c. iii. dial. 2.) The balista, or balistarium, was in the form of a bow, and the profile of the baluster or ballister is also in the form of a bow. The Norman-French word for a crossbow is arbalastre, and the modern French word for baluster is balustre. There is so much resemblance in the form of the two objects, and in the words by which they are expressed, that we are of opinion that the word baluster, or balister, is derived from the Roman engine of war balista, or balistarium.

The baluster is a peculiar kind of column, of the form of an ancient bow in its profile; it is employed in balustrades. [BALUSTRADE.] The baluster has of late years been formed after the model of Greek and Roman columns. Balusters are placed on a plinth, and are surmounted with a cornice. (See the published works of Palladio, Vignola, Scamozzi, and others.) The proportions of balusters are given in the work of Sir William Chambers on Architecture, where they are proportioned to the orders, and are made heavier or lighter according to their destination; the heaviest balusters are given to the Tuscan, and the lightest to the Corinthian and Composite orders.

BALUSTRADE, the termination of a modern edifice. There does not appear to be any example of a balustrade in the remains of antiquity now existing; although there are examples of railing or fencing. Balustrades are most commonly placed over the cornices of large edifices, after the manner of a parapet, as at the Banqueting House at Whitehall, St. Paul's cathedral, London, and on Blackfriars and Westminster bridges when they were first erected, though these have been long since removed. Balustrades are not only employed in large edifices, above the orders of architecture, but also to inclose stairs, terraces, altars, fonts, and the balconies of houses. The balusters forming a balustrade are placed on a plinth, at equal distances from one another, with a small opening between them; they support a cornice, and are divided at intervals by a pedestal. (For the proportions of a balustrade over an order of columns, see Chambers' 'Architecture.') When a balustrade is placed over an order of columns, it is usual to set the die of the pedestal over the columns, making the breadth of the die equal to the breadth of the shaft. Balustrades are made of iron and wood, as well as stone. In Italy balustrades are of very frequent occurrence, and of prodigious extent. At Frascati there is a balustrade in the Villa Conti, more than 2000 feet in length. The colonnade of St. Peter's, by Bernini, is surmounted with a balustrade. But perhaps the most elegant balustrade in Rome is at the Villa Albani; the form of the baluster in this differs from the old and bow-shaped baluster commonly employed. Barry introduced balusters imitated from Italian forms, and his example has been since frequently followed.

Examples of Balusters employed in four different structures.



Old Westminster Bridge. Villa Albani. Wooden bow-shaped Baluster. Blackfriars Bridge (now removed).

The cuts represent four kinds of baluster; one like the bow above-mentioned, the others as if the bow-like baluster had been cut in two horizontally to form two balusters. The latter is the baluster most commonly used; but the former appears to be the oldest and earliest form; an example of it may be seen in some of the galleries of old wooden buildings in England and other countries of Europe. The court-yard at Chillingham Castle, and the gate of honour leading into Caius College, Cambridge, present examples of the bow-like baluster. There are examples also in the works of Palladio, Vignola, Scamozzi, and other architects of Italy.

BAN, BANNS. These words are found in many of the modern languages of Europe in various senses. But as the idea of 'publication' or 'proclamation' runs through them all, it is probable that it is the ancient word *ban* still preserved in the Gaelic and the modern Welsh in the simple sense of 'proclaiming.'

As a part of the common speech of the English nation, the word is now so rarely used that it is put into some glossaries of provincial or archaical words, as if it were obsolete, or confined to some particular districts or particular classes. Yet, both as a substantive and a verb, it is found in some of our best writers; among the poets, Spenser, Marlowe, and Shakspere; and among prose-writers, Knolles and Hooker. By these writers however it is not used in its original sense of 'proclamation,' but in a sense which it has acquired by its use in proclamations of a particular kind; and it is in this secondary sense only that it now occurs in common language, to denote cursing, denouncing woe and mischief against one who has offended. A single quotation from Shakspere's tale of 'Venus and Adonis' will show precisely how it is used by writers who have employed it, and by the people from whose lips it may still sometimes be heard:

> "All swollen with chafing down Adonis sits,
> *Banning* the boisterous and unruly beast.

The improvement of English manners having driven out the practice, the word has nearly disappeared. But in the middle ages the practice was countenanced by such high authority, that we cannot wonder at its having prevailed in the more ordinary ranks and affairs of life.

When churches and monasteries were founded, writings were usually drawn up, specifying with what lands the founder and other early benefactors endowed them; and these instruments often conclude with imprecatory sentences in which torments here and hereafter are invoked on any one who should attempt to divert the lands from the purposes for which they were bestowed. It seems that what we now read in these instruments was openly pronounced in the face of the Church and the world by the donors, with certain accompanying ceremonies. Matthew Paris, a monk of St. Albans, who has left one of the best of the early chronicles of English affairs, relates that when King Henry III. had refounded the church of Westminster, he went into the chapel of St. Catherine, where a large assembly of prelates and nobles was collected to receive him. The prelates were dressed in full pontificals, and each held a candle in his hand. The king advanced to the altar, and laying his hand on the Holy Evangelists, pronounced a sentence of excommunication against all who should deprive the church of anything which he had given it, or of any of its rights. When the king had finished, the prelates cast down the candles which they held, and while they lay upon the pavement, smoking and stinking (we use the words of the author who relates the transaction), the Archbishop of Canterbury said aloud: "Thus, thus may the condemned souls of those who shall violate or unfavourably interpret these rights be extinguished, smoke, and stink;" when all present, but the king especially, shouted out "Amen, amen."

This, in the English phrase, was the *banning* of the middle ages. Nor was it confined to ecclesiastical affairs. King Henry III., in the ninth year of his reign, renewed the grant of Magna Charta. In the course of the struggle which was going on in the former half of the 13th century between the king and the barons, other charters of liberties were granted. But for the preservation of that which the barons knew was only extorted, the strongest guarantee was required; and the king was induced to preside at a great assembly of nobles and prelates, when the archbishop pronounced a solemn sentence of excommunication against all persons of whatever degree who should violate the charters. This was done in Westminster Hall on the 3rd day of May 1253. The transaction was made matter of public record, and is preserved in the great collection of national documents called Rymer's 'Fœdera.'

But besides these general *bannings*, particular persons who escaped from justice or who opposed themselves to the sentence of the Church, were sometimes *banned* or placed under a *ban*. In the history of English affairs, one of the most remarkable instances of this kind is the case of Guido de Montfort. This Guido was the son of Simon de Montfort, earl of Leicester, and grandson of King John. In the troubles of England, in which his father lost his life, no one had been more active in the king's service than Henry of Almaine, another grandson of King John, and the eldest son of Richard, that king's younger son, who had been elected King of the Romans. This young prince, being at Viterbo in Italy, and present at a religious service in one of the churches of that city, was suddenly assaulted by Guido de Montfort, and slain upon the spot. A general detestation of the crime was felt throughout Europe. Dante has placed the murderer in the 'Inferno:'

"He in God's bosom smote
The heart still reverenced on the banks of Thames."

The murderer escaped. Among the rumours of the time, one was that he was wandering in Norway. This man the pope placed under a *ban;* that is, he issued a proclamation requiring that no person should protect, counsel, or assist him; that no person should hold any intercourse with him of any kind, except perhaps some little might be allowed for the good of his soul; that all who harboured him should fall under an interdict; and that if any person were bound to him by any oath of fidelity, he was absolved of the oath. This was promulgated throughout Europe. A papal bull in which the proclamation is set forth still exists among the public records in the chapter-house at Westminster. A copy of it is in Rymer's 'Fœdera.' The pope uses the very expression *forbannimus;* "Guidonem etiam forbannimus."

This species of *banning* is what is meant when we read of persons or cities being placed under the *ban of the empire;* a phrase not unfrequently occurring in writers on the affairs of Germany. Persons or cities who opposed themselves to the general voice of the confederation were by some public act, like those which have been described, cut off from society, and deprived of rank, title, privileges, and property.

It is manifest that out of this use of the word has sprung that popular sense in which now only the word is ever heard among us, as well as the Italian *bandire*, French *bannir*, and the English *banish*.

In some parts of England, before the Reformation, an inferior species of *banning* was practised by the parish priests. "In the Marches of Wales," says Tyndal in his work against the Romish Church, entitled 'The Obedyence of a Christen Man,' 1534, "it is the manner, if any man have an ox or a cow stolen, he cometh to the curate and desireth him to curse the stealer; and he commands the parish to give him, every man, God's curse, and his; 'God's curse and mine have he,' sayeth every man in the parish." Stowe relates that, in 1299, the Dean of St. Paul's accursed at Paul's Cross all those who had searched in the church of St. Martin in the Fields for a hoard of gold. ('London,' in the account of Farringdon Ward within.) Tyndal argues against the practice, as he does against the excommunicatory power in general. Yet something like it seems to be still retained in the Commination Service of the English Church.

In France the popular language has not been influenced by this application of the word *ban* to the same extent with the English. With them the idea of *publication* prevails over that of *denouncement*, and they call the public cry by which men are called to a sale of merchandise, especially when it is done by beat of drum, a *ban*. In time of war, a proclamation through the ranks of an army is the *ban*. In Artois and some parts of Picardy the public bell is called the *ban-cloque*, or *cloche à ban*, as being rung to summon people to their assemblies. When those who held of the king were summoned to attend him in his wars, they were the *ban*, and tenants of the secondary rank the *arriere-ban;* and out of this feudal use of the term arose the expressions *four à ban*, and *moulin à ban*, for a lord's bakehouse, or a lord's mill, at which the tenants of a manor (as is the case in some parts of England) were bound to bake their bread or to grind their corn. The *banlieue* of a city is a district around it, usually, but not always, a league on all sides, through which the proclamation of the principal judge of the place has authority. A person submitting to exile is said to *keep his ban*, and he who returns home without a recall *breaks his ban*.

The French use the word as the English do, when they speak of the *ban*, or, as we speak and write it, the *banns* of marriage. This is the public proclamation which the law requires of the intention of the parties named to enter into the marriage covenant, when the parties intend to be married with the rites of the church of England. The law of the ancient French and of the English church is in this respect the same. The proclamation must be made on three successive Sundays in the church, during the time of the celebration of public worship, when it is presumed that the whole parish is present.

The intent of this provision is two-fold: 1. To prevent clandestine marriages, and marriages between parties not free from the marriage contract, parties within the prohibited degrees of kindred, minors, or excommunicates; and, 2. To save the contracting parties from precipitancy, who by this provision are compelled to suffer some weeks to pass between the consent privately given and received between themselves and the marriage. Both these objects are of importance, and ought to be secured by law; and provision is made for a due publicity in all other cases of sectarian or civil marriage. The *ban*, or *banns*, may, however be dispensed with. In that case a licence is obtained from some person who is authorised by the bishop of the diocese to grant it, by which licence the parties are allowed to marry in the church or chapel of the parish or parochial chapelry in which either of them resides, in which marriages are wont to be celebrated, without the publication of banns. The law, however, takes care to ensure the objects for which the publication of banns was devised, by requiring oaths to be taken by the party applying for the licence, and certificates of consent of parents or guardians in the case of minors. Special licences not only dispense with the publication of banns, but allow the parties to marry at any convenient time or place. These are granted only by the Archbishop of Canterbury, in virtue of a statute made in the twenty-fifth year of Henry VIII., entitled an Act concerning Peter-Pence and dispensations. It is not known when this practice began, but it is undoubtedly very ancient. Some have supposed that it is alluded to in a passage of Tertullian.

BANCO. [BANK.]

BAND, in Architecture, a flat moulding, with a vertical face slightly projecting beyond the vertical or curved face of any moulding or parts of an edifice to which it is attached. It is very extensively employed in edifices, and is used apparently to bind parts of buildings together, as in the bands which are employed to bind the triglyphs of a Doric architrave. This moulding is most frequently used in the basement story of a building, where it becomes a bold and striking feature: (see the published designs of Palladio, Vignola, Scamozzi, and others.) It is for the most part plain, though sometimes enriched. The term band and bandelet, little band, is often applied to what is more properly speaking a fillet. The band is, however, broader in proportion than the fillet. This moulding is also employed to encircle the shafts of columns [COLUMN; RUSTICATED WORK]; the palace of the Luxembourg at Paris, and the Pitti palace at Florence, present very remarkable examples of banded columns. Bands were frequently employed to encircle the columns of Norman, and First-pointed, and occasionally the Middle-pointed styles of Gothic architecture. Vitruvius calls the band *tænia* and *fascia;* fascia is a term applied also to the flat faces of the architrave. A plain band is often placed in both public and private buildings, to mark the principal floors.

BANDAGE is a term employed in surgery to designate the bands or strips of cloth by which dressings are kept to wounds, separated parts are brought together, blood-vessels compressed, and weak and protruding parts of the body are supported and retained in their natural position. Bandages are commonly composed of flannel, calico, and linen cut into different shapes, according to the parts to which they are applied, and the purposes for which they are required. Thus the bandage often employed in fractures of the upper and lower extremities, and called eighteen or many-tailed bandage, is composed of a longitudinal piece of calico or linen, with transverse pieces, or tails, to fold over the injured part. Another bandage resembles in shape the letter T, and is called the T bandage. But the most common form of bandage, and one available in almost every case, is a long strip or ribbon of calico or flannel, varying in width from two to six inches. Previous to its application it is rolled together, and hence in surgical language is called *roller*, and the application of a bandage is called *rolling*. Of late years, ribbons of stocking-net, commonly called elastic web bandages, have been much used, and they appear peculiarly adapted for the purpose, as their elasticity prevents injurious consequences on any sudden increase of the size of the part to which they are applied. On the same principle caoutchouc or India-rubber, interwoven with silk and cotton, is now frequently employed in the construction of bandages.

The proper employment and management of bandages is an extremely important part of surgical knowledge, for after most operations and accidents, and in many serious local diseases and deformities, the assistance of bandages is required, and on their proper application the successful issue of the case frequently depends. The great object in the common use of the bandage is to give equal and uniform support to the part to which it is applied, and it is of course essential that it should not be easily displaced or deranged by any movement of the patient. The bandage should be put on firmly, so as not to produce pain, but to afford gentle and easy support; and above all it should never be tight in some parts and loose in others, as by partial compression of a limb mortification is easily produced. The art of bandaging has been much neglected in this country. In many of the continental schools, particularly in Germany, distinct courses of instruction have long been given on bandages, and students are required to practise their application in the presence of the teacher. At the present time more attention is paid to this subject in the London schools of surgery, but it would be well if a knowledge of the proper way of applying bandages in all cases of injury was required from every candidate for a surgical diploma.

BANDALEER. [ARMS.]

BANDANAS, or BANDANNAS, a term originally applied to a peculiar kind of silk handkerchief made by the Hindus, is the name now commonly given to silk and cotton handkerchiefs manufactured in this country, and decorated with patterns of similar character, though by a very different process. The distinguishing peculiarity of a bandana handkerchief is that it has a uniformly dyed ground, usually of bright red or blue, ornamented with circular, square, lozenge-shaped, or other simple figures, either white or yellow. These spots are produced, in real Indian bandanas, by tying up the parts intended to be white or yellow with bits of thread before exposing the handkerchief to the action of the dye, and thus protecting them from it. Rude as this process appears, British manufacturers were, owing to the difficulty of imparting a sufficiently durable ground-colour by the ordinary process of calico-printing, unable to imitate Indian bandanas successfully, until a plan was contrived for dyeing the whole surface, and afterwards discharging the colour from the spots forming the pattern by the agency of chlorine. This plan was invented by M. Kœchlin, of Mühlhausen, in 1810, and has been carried into effect on a large scale at the Barrowfield Dye-works near Glasgow, by Messrs. Monteith and Co., with a degree of perfection far exceeding the original Oriental bandanas.

The pieces of cotton cloth being dyed of the requisite colour, they are taken to an apartment containing a range of powerful hydraulic discharging-presses, each of which has a roller at the back, to receive the cloth to be operated upon, and another in front, to receive it after the pattern has been discharged; the intervening portion of the cloth resting upon the bed-plate of the press, which is about a yard square, or equal in size to a single handkerchief. This bed-plate is formed of lead, perfectly smooth and even, and is perforated with holes corresponding with the white spots of the desired pattern; and a similar plate, perforated in like manner, is fixed parallel with, but at a short distance above it. Fourteen pieces of dyed cloth, when laid carefully upon one another, are rolled together upon the back roller of the press, and acted upon simultaneously; and, when their ends are drawn over the bed-plate and secured to the foremost roller, the hydraulic apparatus is brought into action, so that the bed-plate, with the fourteen thicknesses of cloth lying upon it, is raised and pressed with immense force against the upper plate, which is firmly fixed in the press. The bleaching-liquid, which is a solution of chloride of lime, is then poured into a trough connected with the upper plate; and finding its way through the perforations of the pattern, percolates through the fourteen thicknesses of cloth, and escapes through the perforations of the lower plate, its passage through the cloth being sometimes facilitated by a powerful current of air. The extreme tightness with which the dyed cloth is compressed prevents the action of the bleaching-liquid from extending beyond the perforations; and as mechanical contrivances are adopted to ensure the perfect tallying of the perforations in the two leaden plates, the pattern produced by them is very accurately transferred to the cloth. After allowing a few minutes for the action of the bleaching-liquor, it is drawn off, the pressure is removed, and the portion of cloth which has been operated upon is wound on to the front roller. A second portion is then drawn forward upon the bed-plate, for a repetition of the process. By the use of certain chemical liquids, the discharged spots may be made yellow instead of white; and by such an arrangement of the pattern and of the channels for conducting the discharging fluid as will allow two fluids to be used independently of each other, some parts of the pattern may be made white, and others yellow by one operation. In the establishment above-mentioned there are (or were a few years ago) sixteen presses for the production of bandanas; when these are in full work the period required for the complete discharge of the colour in the first press is equal to that required for bringing the remaining fifteen into action, so that one discharger, with his assistants, can keep the whole in constant operation. The whole routine of operations occupies about ten minutes, so that the sixteen presses (each producing fourteen handkerchiefs at each operation) will produce 224 handkerchiefs at each time of working, or upwards of 14,000 in a day of ten hours—requiring, meanwhile, the services of only four men.

The fluctuations of fashion have led to the partial disuse of the bandana style of handkerchief within the last few years; but the process remains as valuable as ever, and applicable to a large variety of goods. [BLEACHING; CALICO PRINTING; DYEING.]

BANDES NOIRES. This appellation was first given to a body of German foot-soldiers, who were employed in the Italian wars by Louis XII. of France, who formed a portion of the troops called Grand Companies. Robertson alludes to them in his 'History of Charles V.' (edit. 4to. 1769, vol. i. p. 113.) They received their name from carrying black ensigns after the death of a favourite commander. (Père Daniel, 'Hist. de la Milice Françoise,' 4to. Par. 1721, tom. ii. p. 383.) Another body of troops, formed of Italians, afterwards took the same name from the same cause, *Le Bande Nère*, or, as Père Daniel calls them, *Les Bandes Noires Italiennes*, to distinguish them from the Germans. Père Daniel adds, that the French regiment of Piedmont, which had served for a long while in Italy, also took the appellation of *Bandes Noires*, after the death of their colonel, the Comte de Brissac, in 1569. The colours of that regiment, he adds, continued to his time to be black, with a white cross.

The Grand Companies were foreign mercenaries, in a great measure raised from the vassalage of Germany, and sold by their lords to whoever could pay for them. It is no wonder that such troops should have been addicted to plunder and even greater atrocities. From France itself they were led into Spain by Du Guesclin, to the support of Henry de Trastamare against Philip the Cruel and the English Black Prince, and never afterwards figured in that country; but in Italy they continued to exist for nearly another century.

BANDITTI. This word, though seldom used by the Italians in our sense, for 'bands of robbers,' is derived from the Italian verb *bandire*, to banish or put to the ban, whence the participle *bandito*, banished or outlawed and the substantive *bandito*, an outlawed man (plural *banditi*), or outlawed men. Correctly, therefore, the word should not be banditti, but banditi. The term seems to have been introduced into our language at least as early as the time of Shakspere; but whoever first imported it and confined its signification to robbers, departed from the original extensive sense of the word, which means a man banished on any account, as for political delinquencies or opinions, plots, religious notions, partisanship, &c. &c. Thus, after Danté and the Ghibellines were expelled from Florence by the Guelphs, they might be called *banditi*, though they were honourable men, representing a defeated political party or faction, and never robbers. Bembo and other *teste di lingua*, or classical writers, who form authority on the subject of Italian idiom, employ the term *banditi* almost exclusively in speaking of political exiles. The great Tuscan dictionary *della Crusca* gives *esiliato* as the synonym of *bandito*, and *exilio damnatus* as the Latin for both. In the 'Dic. di Firenze,' 1819, the definition is an outlaw, an exile, a highwayman. In the south of Italy, the only part of the peninsula where such lawless associations have existed for many years, the robbers are popularly called *briganti*, and never, by any chance, banditi. The French, during their long and sanguinary warfare for the subjugation of Calabria, called by the name of *brigands* both those who were professional robbers, and those who were partisans of the Bourbon King of Naples, Ferdinand, whom the arms of the French had driven out of his continental dominions to Sicily.

These organised bands of robbers have been fostered in Italy by the mountainous nature of a great part of the peninsula, by the division of the country into numerous small states, which too often enabled the robbers, by crossing a frontier, to put themselves in safety; by frequent revolutions, and by weak governments. In modern days, however, their excesses have almost been confined to Lower Italy, the States of the Church, and the kingdom of Naples, and to the islands of Sicily and Sardinia; and regular or numerous bands of robbers have been unknown in Upper Italy, in Lombardy, Piedmont, and Tuscany, for many years. Their principal haunts in recent times have been the country about the frontiers of the Roman and Neapolitan states, from the southern end of the Pontine marshes to the districts of Terracina, Itri, and Pondi; and the valley of the Ponte di Bovino, a narrow mountain-pass, through which runs the high road from Naples, the capital of the kingdom, to the vast plains of Apulia, and the rich provinces of Bari, Lecce, and the Terra d'Otranto. In the first of these positions they were beaten up and almost exterminated by the Austrian troops in 1823, and a little later the valley of Bovino was wholly cleared of them. There have been occasionally highway robberies since then; but organised societies, with their captains, their lieutenants, and chaplains, like those between 1812 and 1823, have not been again formed, except, for a time, during the political agitation of 1848. The most remarkable Italian bandit chiefs of later times were the three brothers Vardarelli, and Don Ciro Anicchiarico. They were all Neapolitans, and the last of them (Don Ciro) a priest, an abbé, and a man of considerable education, who was accustomed to celebrate mass to his band on solemn occasions, and who quoted Latin and Virgil in defences that he sent in to the judicial authorities. The history of this priest-robber, who, not contented with being a successful leader of banditti, which he was for many years, put himself at the head of a secret political society, or rather a series of secret societies, that aimed at nothing less than entirely revolutionising the whole of Italy from the extremity of Calabria to the Alps, and establishing a federal republic, is one of the most astonishing authenticated records of modern times. In January 1818 he attempted a revolutionary movement, but it was suppressed easily, and he was captured and executed.

During the Peninsular War, the general insecurity of the country occasioned the formation of numerous bands of brigands; as they occasionally attacked the French, they endeavoured to cover their crimes under the pretence of being guerillas, but plunder from any party was their main object. With the restoration of order they were suppressed. Neither banditti nor brigands, can exist in a well-regulated, civilised country, where every individual is interested in supporting the supremacy of the law. Wherever such bands exist, we may be certain that the government, and probably the laws, are harsh, oppressive, and unjust. They are unmistakeable proofs of want of true civilisation.

BANIA'NS. The word Banian is a corruption of the Sanscrit *banij*, or *banik*, 'a merchant, a trader,' and is the term by which Hindoos visiting foreign countries for mercantile purposes are generally designated. We find Hindoo merchants noticed at an early period during the Middle Ages in several of the most distinguished trading towns of the East. Marco Polo mentions Hindoos among the foreign traders who visited the fair of Tabriz; and in speaking of Aden, he describes it as "an excellent port, frequented by ships arriving from India with spices and drugs." He was acquainted with the mode in which these commodities were transported from Aden to Lower Egypt, namely, first on Arabian vessels up the Red Sea, to an Egyptian sea-port (Kosseir); thence by camels to a place on the Nile (Kus; afterwards to Kene); and from thence, on boats, down the river to Cairo, and finally to Alexandria. Indian merchants appear also to have settled, during the Middle Ages, on the eastern coast of Africa; Vasco de Gama, on his first voyage, met with several Indian trading-vessels in the port of Melinde (De Barros, 'Asia,' Dec. I. liv. iv. c. 5); and it is not improbable that the information which they afforded may have been of material utility to the early Portuguese navigators in discovering the passage by sea to India. In some of the principal towns of Persia and Arabia, the Banians appear to have sometimes formed a considerable class in society, and to have possessed much political influence. It is said that the Portuguese were driven from their possessions at Muscat through the treachery of a Banian, who thus resented an insult offered to his family. (Niebuhr, 'Beschreibung von Arabien,' p. 297.) In 1765 there were no more than twenty Hindoo merchants settled at Shiraz; but a new caravanserai was at that time built on purpose to be appropriated to their accommodation, in order to induce them to visit Shiraz in greater numbers. Some Hindoos are settled as far to the north and west as Astrakhan. (Niebuhr's 'Reisebeschreibung,' &c. vol. ii. p. 270.) The Banians do not at the present day form a distinct class or caste in India, nor are they accounted as such in the ancient Hindoo law-codes. Some travellers, for example, Tavernier ('Voyages des Indes,' liv. iii. c. 3), have used the name Banian as synonymous with Vaisya, the designation of the whole caste of merchants, husbandmen, and mechanics; but this seems unsupported by Oriental authority. They, however, form a class, adopt a peculiar and picturesque costume, and are remarkably strict in observing the fasts prescribed by their religion, even on their sea-voyages altogether refusing to eat flesh, whence the English sailors have derived 'Banyan-days,' for those when meat is not served out. They also have now a character for great integrity in their commercial transactions, which they have extended from Bombay to Cashmir.

BANISHMENT, expulsion from any country or place by the judgment of some court or other competent authority.

The term has its root in the word *ban*, a word of frequent use in the middle ages, having the various significations of a public edict or interdict, a proclamation, a jurisdiction and the district within it, and a judicial punishment. Hence a person excluded from any territory by public authority was said to be banished—*bannitus, in bannum missus.* (Ducange, *voc.* 'Bannire, Bannum;' Pasquier, 'Recherches,' pp. 127, 732.)

As a punishment for crimes, compulsory banishment is unknown to the ancient law of England, although voluntary exile, in order to escape other punishment, was sometimes permitted. [ABJURATION.] The crown has always exercised, in certain emergencies, the prerogative of restraining a subject from leaving the realm; but it is a known maxim of the common law, that no subject, however criminal, shall be sent out of it without his own consent, or by authority of parliament. It is accordingly declared by the Great Charter, "that no freeman shall be exiled unless by the judgment of his peers or the law of the land."

There are, however, not wanting instances in our history of an irregular exercise of the power of banishing an obnoxious subject by the mere authority of the crown; and in the case of parliamentary impeachment for a misdemeanor, perpetual exile has been made part of the sentence of the House of Lords with the assent of the king. (Sir Giles Mompesson's case, *temp.* James I., reported by Rushworth and Selden; Comyn's 'Digest,' title 'Parliament,' l. 44.) It may be noticed also, that aliens and Jews (formerly regarded as aliens) have, in many instances, been banished by royal proclamation.

Banishment is said to have been first introduced as a punishment for crime by a statute in the thirty-ninth year of Elizabeth, by which it was enacted, that "such rogues as were dangerous to the inferior people should be banished the realm;" but an instance occurs in an early statute of uncertain date (usually printed immediately after one of the eighteenth of Edward II.), by which butchers who sold unsound meat might be compelled to abjure the village or town in which the offence was committed. At a much later period the punishment called transportation was sanctioned by the legislature, and in many cases made the condition on which the crown has consented to pardon a capital offence. [TRANSPORTATION.]

Banishment, in some form, has been prevalent in the criminal law of most nations, ancient as well as modern. Among the Greeks two kinds were in use:—1. Perpetual exile (φυγή), attended with confiscation of property, and employed as a punishment for crimes; 2. Ostracism, as it was called at Athens, or Petalism, the term in use at Syracuse, a temporary expulsion, unaccompanied by loss of property, and inflicted sometimes upon persons whose influence, arising either from great wealth or eminent merit, made them the objects of popular suspicion or jealousy.

Among the Romans there were three forms of banishment:—1. *Relegation*, which was the mildest form, obliged the offender to reside in some assigned place abroad, either for a fixed time or for life, but subjected him to no other civil disability or loss. Of this nature was the banishment to which we owe the plaintive poetry of Ovid. 2. *Exile*, or the 'interdiction of fire and water,' prescribed no particular place of abode, nor did it directly or expressly sentence the culprit to expatriation; but by depriving him of every possible means of living in his own country, it indirectly compelled him to seek another, and eventually stripped him of the rights of citizenship. 3. The last kind of banishment, *Deportation*, was introduced in place of the interdiction, and by it the criminal incurred all the civil forfeitures of exile, and was usually conveyed to some remote island (Tacit. 'Hist.' i. 2), in which his life was rendered painful by fetters, by forced labour, or by the natural effects of the climate. Deportation therefore differed little from the punishment known among us as transportation, except as far as regards the healthiness of the spot selected; and it was further attended by the same consequences of civil death during the continuance of the term of punishment. Hence it was that the day of the exile's return was called his second birth-day. (Heinecc., 'Antiq. Rom. Syntagma,' lib. i. tit. 16; 'Digest,' lib. xlviii. tit. 22.)

BANISTER is a corrupt term for baluster [BALUSTER]. It is used to express the wooden railings inclosing the stairs of a house.

BANK, in barbarous Latin *bancus*, literally signifies a bench or high seat; but as a legal term it denotes a seat of judgment, or tribunal for the administration of justice. In a rude state of society, justice is usually administered in the open air, and the judges are placed in an elevated situation both for convenience and dignity. Thus it appears that the ancient Britons were accustomed to construct mounds or benches of turf for the accommodation of their superior judges. (Spelman, *ad verbum.*) It is clear, however, that in very early times in this country there was a distinction between those superior judicial officers who, for the sake of eminence, sat upon a bench or tribunal, and the judges of inferior courts, such as hundred courts and courts baron, the latter being analogous to the *judices pedanei* of the Roman law—a kind of inferior judges, whose duties are not very clearly defined, but who are expressly stated to have derived their denomination *a pedibus, quod pede plano judicarent non pro tribunali.* (Calvin's 'Lexicon Juridicum,' *voc.* 'Pedanei.')

In consequence of this distinction, the judges, who were immediately appointed by the crown to administer justice in the superior courts of common law, were in process of time called justices of the bench, or, as they are always styled in records, *justiciarii de banco.* This term, in former times, denoted the judges of a peculiar court held at Westminster, which is mentioned in records of the reign of Richard I., and must therefore have made its appearance, under the name of *bancum* or bench, not long after the Conquest. This court probably derived its name from its stationary character, being permanently held at Westminster, whereas the *curia* or *aula regis* followed the person of the sovereign (Maddox's 'History of the Exchequer,' p. 539), and may have been the origin of the modern Court of Common Pleas, the judges of which court retain the technical title of 'Justices of the Bench at Westminster' to the present day. The formal title of the Queen's Bench judges is "the Justices assigned to hold pleas in the court of the Queen before the Queen herself." For many centuries, however, the judges of both courts have been described in Acts of Parliament and records in general terms as "the judges of either bench" (*judices utriusque banci*); but the barons of the Court of Exchequer have never been denominated judges of the bench, though, in popular language, a new baron, on his creation, is like the other judges, said to be raised to the bench.

The phrase of sitting *in banco*, or in bank, merely denotes the sittings of the court during the law terms, when the judges sit together upon their several benches. In this sense it is used by Glanville, who wrote in the reign of Henry II., and who enumerates certain acts to be done by justices *in banco sedentibus.* Sittings *in banc* after term are held by virtue of statutes authorising the courts to appoint such sittings. *Days in bank*, or *Return days*, are days particularly appointed when parties served with writs are to make their appearance in full court, on the return of the writ in real actions. The day in bank is so called in opposition to the day at *Nisi Prius*, when a trial by a jury takes place according to the provisions of the statute of Nisi Prius. [ASSIZE.]

BANK; BANKER; BANKING. These three subjects are so intimately connected, that it would hardly be possible to give any clear description of them separately. By the term "bank" is understood the establishment for carrying on the business to be described; the "banker" is the person by whom the business is conducted; and the expression "banking" is commonly used to denote the system upon which that business is managed, and the principles by which it should be governed or regulated.

In all populous and civilised communities, and especially in such as are to any great extent commercial, the business of banking is one in the proper understanding and right conducting of which the public generally is, beyond all other businesses, interested. Errors, however grave, committed by those who are engaged in the business of importing and exporting, or in manufacturing and dealing in goods, are for the most part mischievous only to the parties immediately concerned, and to those with whom they may individually hold commercial relations. But errors with regard to the principles or practice which should govern the trade of banking, extend their evil consequences to a far wider field, and in such cases the mischief cannot fail to be felt in some degree by great numbers of the community.

This fact appears so obvious upon the slightest reflection, that it must afford matter for surprise when we consider in how trifling a degree the better informed among the mercantile body, and even the greater part of those who are actually engaged in the business, have attempted to gain any knowledge of the true theory of banking; while the remaining portions of the community, as well those whose station in life renders attention to matters of business unnecessary, as those whose humble rank affords them no opportunity of acquiring a practical knowledge of extensive money transactions, with but very few exceptions appear to have considered the question as one with which they have no concern. It is foreign to our purpose to enter at large upon the discussion of any of the controverted points connected with the theory of banking. In the few remarks of a general nature that may be here offered, our design will principally be to awaken attention to the subject; while by bringing forward some of the more prominent facts and principles connected with it, we may be able to afford that degree of knowledge which will form the best and most practical groundwork for speculative investigations, and at the same time, we trust, prove a preservative against the mischiefs which are likely to result from plausible fallacies.

We propose to consider the subject of banks and banking under the following heads:

I. Brief historical notices of the origin and progress of banking in various countries of Europe and of the British Colonies, with some account of the present state of banking in the United States of North America.

II. An explanation of the objects and general principles of banking.

III. The history and constitution of the Bank of England.

IV. The art of banking, as carried on by private establishments and joint-stock associations in London and other parts of England, and in Ireland.

V. A description of the Scotch system of banking.

I. *Historical Sketch of the Origin and Progress of Banking.*—The vague notices which are found in ancient history, both sacred and profane, connected with dealings in money as a separate business, appear fully to warrant the belief, now generally held by scholars, that banking, in the sense wherein it is now understood, was but little known or practised in very remote periods. In times when nations were chiefly engaged in pastoral or agricultural pursuits, the trade of banking would hardly suggest itself to anybody as a profitable calling; and until, in the progress of a community towards civilisation, the extent of its commercial dealings had become very considerable, none would be led to give their attention to the occupation of facilitating the money operations of the rest of the mercantile community. At first this office would doubtless be undertaken for others by the more considerable traders, and a further period would elapse before it would become a separate business.

It is probable that the necessity for some such arrangement would be first experienced, in consequence of the different weights, and degrees of fineness, of the coined monies and bullion which would pass, in the course of business, between merchants of different nations. The principal occupation of the money changers mentioned by St. Matthew, was doubtless that of purchasing the coins of one country, and paying for them in those of their own, or of any other people, according to the wants and convenience of their customers. It is likewise probable that they exercised other functions proper to the character of bankers, by taking in and lending out money, for which they either allowed or charged interest (Matthew xxv. 27).

There has been supposed to be some allusion to the operations of Oriental banking in the parable of the slothful servant: "Thou oughtest to have put my money to the exchangers, and then at my coming I should have received my own with usury." The banking of those days probably consisted chiefly in exchanging small coins for large ones, and the money of one country or district for that of another, charging a small commission for the accommodation. But all this is very obscure; and we cannot be said to know anything very certainly upon the question of what was the nature of the money dealings among the ancient Jews.

Greek Banking.—The information which is extant upon the subject of money dealing in ancient Athens may be summed up as follows: A class of persons,—called τραπεζῖται, from the stands or tables (τράπεζαι) at which they attended to do business in the market-place of the city,—were chiefly occupied in changing money, at an Agio—[Agio]: but yet a considerable part of their business consisted in taking money on deposit, allowing interest on it, and of course lending it again, or employing it in some other manner, at higher interest. They sometimes also lent out money of their own on deposits of goods. On the whole they seem to have been a thriving class, and even to have had a system of correspondents and business connections in the chief cities of Greece, and generally to have been held in high estimation. We read of one Pasion, a manumitted slave (afterwards presented with the freedom of the city by the Athenian people), having attained wealth as an Athenian banker: he is stated to have owned land to the value of 20 talents, and besides to have had money at use to the amount of 50 talents, out of which, 11 talents were deposits of his banking customers; or in other words (taking the talent at equal to 250*l.* sterling), his landed property was worth 5000*l.*, the money he had out on interest was 12,500*l.*, and the part of that which came to him from his banking business was 2750*l.* He appears also to have carried on a manufactory of shields or targets, and on one occasion presented the republic with 1000 bucklers and five triremes fully equipped. His name was celebrated; he was a man of unquestioned integrity, and his friendships and connections were extended through the whole of Greece. He is very frequently spoken of by Demosthenes and the contemporary orators ('Oratores Attici,' 1127, 1132, 1224). We find mention also of other eminent bankers. The rate of interest they exacted appears to modern political economy quite enormous: 36 per cent. is stated to have been no unusual amount.

The only trace we believe of an ancient Greek bank of a *public* character occurs at Byzantium, where the republic (at a time of great financial pressure) amongst other devices adopted for the purpose of raising money, established a monopoly of money-changing at a single bank or table, and then let it out to hire (Aristot. 'Œconom.' lib. ii.. p. 502. edit. Paris, 1619). It will be observed that the vast variety of the coins used in the different Greek states necessarily rendered the business of money changer, notes and paper money being unknown and forming no part of the circulation, one of great importance as well as profit.

Roman Banking.—The money dealers at ancient Rome seem to have been divided into two classes: one called *argentarii* (the currency being silver), or *argenteæ mensæ exercitores:* or *argenti distractores:* or *negotiatores stipis argentariæ:* the other class was called *mensarii*, or *mensularii*, or *nummularii*. 1, the argentarii were private money dealers who, in numbers fixed by law, carried on their business consisting chiefly in changing coins, in shops or stalls round the Forum, which appear to have been under the control of the censors, and sold by them in the nature of a monopoly. The earliest mention of this trade occurs, B.C. 350; but it probably must be dated much earlier (Liv. 'Hist.' vii. 21; xl. 51). From certain passages in Cicero's 'Letters,' it has been concluded that the Romans of his times were in fact acquainted with the bill of exchange as a medium for the transmission of money, and the settlement of accounts; and it is said that the argentarii for this purpose were in the habit of receiving money in Rome, and by drawing a bill upon a correspondent in Athens (ex. gra.) to be able thus to transmit without the passing of coin, and with all the ease of modern mercantile and banking transactions. But this, we must own, appears to us to be no more than a fanciful conjecture: the reader must judge for himself by a comparison of the following passages from which this startling inference has been drawn. (Cic. ad Att. xii. 24, 27; xv. 15; v. 15; xi. 1, 24. Cic. 'ad Famil.' ii. 17; iii. 5. Cic. ad 'Quint. Fra. Q.' i. 3. Cic. pro Rabir. 14.) It is more certain that they received deposits, out of which they made the depositor's payments for him; and in that case paid him no interest on the deposit. When a payment was to be made, the depositor either desired the *argentarius* by word of mouth, or in writing, to make it; or money was lodged with the argentarius on the footing of his paying interest for the use of it. In this case it was called *creditum*, in the former *depositum;* the written order to pay, or cheque (as it may perhaps be considered equivalent to) was *perscriptio*. We are told also, that if the person in whose favour the order was made dealt with the same banker, the payment was made by a transfer in the banker's book, called *perscribere*, or merely *scribere*. The *argentarii* also would make payments for persons who had not deposited money previously with them; and on such advances they also made large profits. The books of these people seem to have been kept with great accuracy, and to have been looked upon in the courts of justice as most credible sources of evidence; and the imperial law enforced their production in evidence in the courts when necessary. They also not uncommonly joined with their proper business, that of acting as agents or brokers at sales and auctions. In the times of the later emperors, this body was under the superintendence of the *præfectus urbi*. Several of the ancient writers speak of the occupation of *argentarius* as respectable and even honourable. (Cic. pro Cæcin. 4; Aurel. Vict. 72, &c.) Suetonius commemorates the fact, that the grandfather of the Emperor Vespasian was a *coactor*, or collecting clerk at a banker's; and that his father followed the business of money lending with the troops stationed among the Helvetii; the biographer's general object manifestly not being to cast any imputation on the emperor's ancestry. However, the *argentarii* in Latin comedy, seem to have been always treated as contemptible; but perhaps this is no more than what may be said of the stage soldier, who is always made to be a boaster, and stage father, who is conventionally a tyrant and close-fist.

2. The *mensarii* were distinguished from the *argentarii*, in being appointed by the state; like them, they had their banks or tables

round the Forum; and their business was to lend the money of the state to persons who could give security. The system arose out of circumstances of urgent pecuniary and political pressure. The plebeians, about B.C. 352, were desperately indebted: it was customary for them to borrow from one person in order to pay off a debt to some other person, and so on, and it was to meet this state of things that *quinqueviri mensarii* were appointed with power to make loans on cattle or land; and state officers of this description, triumviri mensarii, continued to be appointed from time to time and for a limited period, in seasons of monetary distress all through the republican period. The *mensularii*, or *nummularii* were a permanent body also appointed by the government, and more properly approached to modern notions of what bankers are, or ought to be; both the treasury of the government and individuals appear to have deposited money with them, on which they paid and received interest. They were also engaged like the *argentarii* in changing coins for a commission, and further, in examining and deciding upon the intrinsic fineness and genuineness of all coin submitted to them. Under the empire they formed a distinct corporation, and, like the argentarii, were subject to the *præfectus urbi.* There is a curious account of a collapse of credit at imperial Rome, and of the measures taken by the government for the resuscitation of confidence, in Tacit. 'Annal.,' vi. 17.

Mensarii are also mentioned as being appointed by the people in the city of Temnos, in Asia Minor, (Cic. 'pro Flac. 19.'

During the middle ages, in which commerce was but little developed, there could be no field open for banking business; but on the revival of commerce in the 12th century, and when the cities of Italy engrossed nearly all the trade of Europe, the necessity again arose for the employment of bankers. These at first carried on their business in the public market-places, or exchanges, where their dealings were conducted on benches, whence the origin of the word bank, from *banco*, the Italian word for a bench. The successful manufacturing efforts of the Florentines brought them into commercial dealings with different countries in Europe, and thence arose the establishment of banks. In a short time Florence became the centre of the money transactions of every commercial country in Europe, and her merchants and bankers accumulated great wealth.

The banks here mentioned were private establishments. The earliest public bank established in modern Europe was that of Venice, which was founded in 1157. Its origin was briefly this: Between 1156 and 1171, on the occasion of great impending danger from a war with the Greek empire, at the head of which was Manuel Comnenus, money being greatly wanted by the republic to meet the exigencies of the crisis, forced loans were levied on the most wealthy citizens, and the Chamber of Loans (la Camera degl' imprestiti) was established, to which the contributors were made creditors at an annual interest of four per cent.: a rate far below the standard of the age. These creditors, in process of time, were incorporated into a company for the management of their joint concerns, and thus formed the basis upon which was afterwards erected the bank of Venice. This method, by which the above-named loan was acknowledged, is believed to be the earliest instance on record of the funding system, and the first example, in any country, of a permanent national debt. The bank was therefore an incorporation of public creditors, to whom privileges were given by the state as some compensation for the withholding of their funds. The public debt was made transferable in the books of the bank, in the same manner as the national debt of England is transferable at the present time; it was made obligatory upon the merchants to make their contracts and draw their bills in bank-money, and not in the current money of the city. [For an explanation of this difference, see AGIO.] The effect of this regulation was, that all payments of that nature were made by a transfer from one name to another in the bank-accounts, of the funds deposited in its coffers. This establishment, which was always essentially a bank of deposit and not of issue—the difference between which functions will be described further on—existed for more than six centuries, or until the subversion of the republic in 1797. Its money at all times bore a premium, or *agio*, over the current money of the city.

About the year 1350, the cloth-merchants of Barcelona, then a wealthy body, added the business of banking to their other commercial pursuits; being authorised so to do by an ordinance of the king of Aragon, which contained the important stipulation, that they should be restricted from acting as bankers until they should have given sufficient security for the liquidation of their engagements. In 1401, a bank was opened by the functionaries of the city, who declared their public funds answerable for the safety of money lodged in their bank, which was a bank of deposit and circulation, the first of the kind established in Europe.

The Bank of Genoa was planned and partially organised in 1345; but was not fully established and brought into action until 1407, when the numerous loans which the republic had contracted with its citizens were consolidated, and formed the nominal capital stock of the bank. This bank received the name of the Chamber of St. George, and its management was intrusted to eight directors, chosen by the proprietors of the stock. As a security for its capital in the hands of the republic, the bank received in pledge the island of Corsica, and several other possessions and dependencies of Genoa. The Bank of St. George was pillaged by the Austrians in 1746; and in 1800, when the French were besieged in Genoa, they appropriated the treasure of the bank to the payment of their troops. Since that time the prosperity of the establishment has been at an end; it is no longer used as a place of deposit for money, and its shareholders are but ill-repaid, by the assignment of a portion of the revenues of the town, for the robberies committed upon them.

The banks of note next established, of which we possess any account, were opened in Holland and in Hamburg in the early part of the 17th century. The most celebrated of these was the Bank of Amsterdam, established in 1609, simply as a bank of deposit, to remedy the inconvenience arising from the great quantity of clipt and worn foreign coin which the extensive trade of the city brought there from all parts of Europe. This bank, which was established under the guarantee of the city, received foreign coin, and the worn coin of the country, at its real intrinsic value, deducting only a small per centage which was necessary for defraying the expense of coinage, and the charges of management. The credit given in the bank books for coin thus received, was called bank-money, to distinguish it from the current money of the place. The regulations of the country directed that all bills drawn upon or negotiated at Amsterdam, of the value of 600 guilders (about 55*l.*) and upwards, must be paid in bank-money. Every merchant was consequently obliged to keep an account with the bank, in order to make his ordinary payments.

The Bank of Amsterdam professed to lend out no part of its deposits, and to possess coin or bullion to the full value of the credits given in its books. The necessary expenses and profits of the establishment were provided for by means of certain fees, payable by the merchants upon opening accounts, and upon making transfers, and from small fines for irregularities. In 1672, the French armies advanced to Utrecht, and a panic at Amsterdam took place; the depositors in great numbers demanded their money, when it was repaid with such ease, that every one was satisfied as to the solvency of the establishment.

In 1775, the treasure in its keeping was estimated to have been 33 millions of florins. In December, 1790, they declared that they should retain ten per cent. of all deposits, and would return none of less amount than 2500 florins. In 1794, on the invasion of the French, the bank was obliged to declare themselves to have lent to the states of Holland and West Friesland, and the West India Company, more than 10,500,000 florins. Bank money, which previously bore an agio of 5 per cent., fell immediately to 16 per cent. below the current money. Thus fell an institution which had obtained, and it was of course thought had deserved, boundless credit.

The Bank of Hamburg was established in 1619, on the model of that of Amsterdam originally. It is purely a deposit bank, for the transfer of sums from the account of one to the account of another of those who deal with it. No deposits, however, are received in coin, but only in bullion. Down to 1845, the bank charged four-ninths, or nearly one-half per cent., for the care and custody of the deposits; but since that date, its charge is one mille for expenses. It advances money on jewels, up to three-fourths of their value. The city is responsible for all deposits, which may be sold by auction if they remain one year and six months without any interest paid; if the value be not claimed within three years, the property in the deposits is lost, and passes to the poor of the city.

Next in point of date among these establishments we find the Bank of England, which was opened in 1694. As we propose to devote a separate section to the description of the principles and practice of this bank, we shall not further notice it in this place.

The Bank of Vienna, established in 1703 as a bank of deposit and circulation, subsequently (1793) became a bank of issue. This institution has now in a great measure lost its commercial character, and has become an engine of the government for managing the public debt and finances.

The notes of the Bank of Vienna, which had become the sole circulating medium in Austria, having fallen to a considerable discount by reason of their excessive quantity, a new bank, called the Austrian National Bank, was established in 1816, with the two-fold object of diminishing the paper currency, and of performing the ordinary banking functions.

The Banks of Berlin and Breslau were erected in 1765, under the sanction of the state. These are banks of deposit and issue, and likewise discount bills of exchange.

During the reign of the Empress Catherine, three different banks were established at St. Petersburg; these were, the Loan Bank, the Assignation Bank, and the Loan Bank for the nobility and towns. The first, which was established in 1772, makes advances upon deposits of bullion and jewels, and allows interest upon all sums deposited for at least a year. The operations of this bank, as a Monte de Piété, are carried on for the profit of the Foundling Hospital in St. Petersburg. The Assignation Bank, opened in St. Petersburg in 1768, and in Moscow in 1770, issues the government paper-money, and is in all respects an imperial establishment. The Loan Bank for the nobility and towns advances money on real security. It is likewise a discount-bank, and acts as an insurance company. The Aid Bank, established in 1797, advances money to relieve estates from mortgages, and to provide for their improvement. The punctual payment of interest upon its advances is enforced by taking their estates from the possession of defaulters until the debt is discharged.

The Commercial Bank of Russia, which was established in 1818, receives deposits of coin and bullion, and has a department for transferring credits from one account to another, in the manner of the banks of Amsterdam and Hamburg. It is also a bank of discount, and makes advances upon merchandise of home production. Its capital, about a million and a half sterling, is declared to be sacred on the part of the Russian government, and free from all taxation, sequestration, or attachment, as well as from calls for assistance on the part of the State. This bank has branches at Moscow, Archangel, and other important commercial towns in the empire.

The Bank of Stockholm, in its present shape, was founded about the year 1688, when its direction was assumed by the Assembly of the States of the kingdom of Sweden, and under their regulations the bank became a bank of deposit, discount, and circulation, the king declaring himself and his successors protectors of the bank, but renouncing all interference in the disposal of the money. Depositors were allowed interest at the rate of 6 per cent.: the deposits, together with notes of circulation, were appropriated to discounts on collateral securities at 8 per cent. The king's revenues were deposited free of interest. The institution obtaining much business, the interest on deposits was gradually reduced, until, by the year 1700, it had reached 2 per cent., whilst the discounts had fallen to 3 per cent. The wars of Charles XII. operated as a drain upon the resources of the bank, and its credit fell, and the king was obliged to make a declaration that no further demands should be made upon it by him until its credit was fully re-established. This effect was shortly afterwards produced, it is said, in consequence of this declaration and the king's adherence to the spirit of it; and the bank was divided into two departments—the Loan and Exchange Banks: the first being in fact an establishment for lending money on certain goods and produce, its own stock, lands, &c.; the other a bank of deposit, discount, and circulation on money deposited. The bank allows 2 per cent. interest; it issues notes and discounts bills of exchange. In 1766 the affairs of the bank fell to a very low state; when it was assisted by the States with a loan of three millions of rix dollars, to pay off the excess of its notes in circulation. Since that period a committee, composed of members of each of the three States—nobles, clergy, and burghers—is appointed triennially to inspect its affairs.

The Bank of France, originally founded in 1800, was placed upon a more solid basis in 1806, when its capital was raised to 90 millions of francs, divided into 90,000 shares or actions, of 1000 francs each. Of these, 67,900 are held by individuals—the remaining 22,100 having been as it were bought in by the bank itself out of surplus profits; and having been cancelled. Down to 1848 therefore its capital amounted to 67,900,000 francs, or 2,716,000*l.*, with a reserve fund of 12,980,750 francs. The bank is now the only authorised source of paper money in France. Its charter and exclusive privileges have been conferred, varied, or continued, by different governments, and under various laws; at present, 1897 is the term fixed at which the terms made with the bank by the public may be put an end to. The bank has branches scattered through the departments. The revolution of 1848 was a period of great crisis to the bank; it had made advances to the provisional government and the municipality of Paris; there was an increasing want of confidence in the existing order of things; and the whole issued in a drain upon the bank for gold, which arrived at such a height that the government at length felt it to be necessary to interfere; and by a decree of March 16, 1848, they authorised the bank to suspend payment in cash, the notes being made a legal tender, and the maximum amount of issues being fixed at 350 millions. This measure also included an authorisation to issue notes of 100 francs and 200 francs each, instead of being restricted to notes for 500 francs, as was the previous rule. But this was not all: for banks having been established in Lyon, Marseille, and other great towns, upon the model of the Bank of France, it was determined that these should become absorbed or incorporated into the Bank of France, and by decrees of the same year, the shareholders in nine banks of this description were permitted to receive, for every 1000 francs of nominal value of their shares, a share of 1000 francs nominal value in the stock of the Bank of France. This raised the capital to 91,250,000 francs, divided into 91,250 shares. In 1851 the bank resumed, and has since maintained, cash payments. The effect of the above-mentioned absorption was to suppress the local circulation of the departments in which the issues of these nine provincial banks were current; and their place has been supplied in some measure by the establishment of branches of the Bank of France. The war with Russia, the drain of silver for the East that has been felt generally in Europe for some years past, and the rage for speculation which to some extent has appeared in France of late years, exposed the bank to considerable difficulties. A law of 9th June, 1857, doubles the capital of the bank, with a view of increasing the strength of its position; that capital now consists of 182,500 shares of 1000 francs each. Till the above date the bank was prohibited from raising the rate of interest, either on loans or discount, above 6 per cent. The consequence was, that for three or four years before the change, all the gold they purchased, being worth more in another market, they were unable to keep up a proper stock of bullion; but now the charge may be whatever the bank deems expedient, except the advances to the government, the interest on which is limited to 3 per cent. as a *maximum*, and in September, October, and November 1857, its rates of discount were to the public generally 8, 9, 10 per cent. respectively. The bank is further authorised to issue notes as low as 50 francs each, and to make advances on railway shares, &c. It is obliged to open an account current with any one who desires. On these accounts no commission is charged; and the chief part of the profits are probably derived from the discount of bills of exchange, which is done on all bills not having more than ninety days or three months to run, and provided they bear three signatures. In 1855 the total amount discounted was 3262 million francs. Besides discounting, the Bank of France advances upon deposits of stock and pledges of a miscellaneous kind. It also undertakes the safe custody of valuables—as plate, jewels, title deeds, &c., charging ⅛ per cent. on the value for every period of six months, and under that, during which the goods, &c., are kept by them. A council of twenty-one members conducts the direction of affairs; namely, a governor and two sub-governors, who are to be nominees of the Emperor; fifteen directors, and three censors, nominated by the shareholders. There is a large surplus capital or rest. The shareholders received a bonus of 200 francs and 272 francs respectively, in each of the years 1855, 1856.

Total circulation of notes from 1848 to 1856 inclusive:—

1848	409,120,000 francs.
1849	431,022,000 "
1850	481,552,000 "
1851	583,040,000 "
1852	689,910,000 "
1853	644,280,000 "
1854	636,970,000 "
1855	612,237,000 "
1856	612,332,000 "

The management of this bank is generally allowed to be admirable; the only objection made is on the score of the too intimate connection with the government. Their management is said to be especially good with respect to the payment of dividends on the government stocks: from seven to ten days is the whole time which they occupy in preparing for the payment of the dividends on each of the quarterly payments. The Bank of England requires a month for this purpose previous to each quarterly dividend day. The contrast is very striking, though of course, the quantity of business to be done in the two cases is enormously different. The Bank of France publishes a monthly debtor and creditor account of its affairs in 'The Moniteur.'

Banks of the United States of North America.—The people of the United States have heretofore suffered largely by the failure of their banking establishments throughout the country; this may be the better imagined when we state that in 1837, as is alleged to be the belief of the best informed authorities, every bank in the Union, without an exception, stopped payment. In 1839-40, another crash occurred, continuing until 1842, when it was supposed about 180 banks fell, including the Bank of the United States. With the view of preventing the evils arising from these disastrous results (which were much aggravated in intensity by reason of the small note circulation, which many of the banks issued largely in nearly all the States), but with least incomplete success in New York, efforts have not been wanting on the part of the government, and measures have passed into law, having this purpose in view. In the state of New York, the banks are said to have been divided into two classes—the incorporated and the free banks; the former, which are incorporated by statute, and whose charters have not yet expired, are obliged to contribute one-half per cent. per annum upon their capital to a security fund, which is applied to the payment of the notes of such of these banks as fail; but this plan (it is said) is now rarely acted upon. Under the free banking system, every one may become a banker who will deposit government securities for the payment of the notes he issues; the lowest sum allowed as such deposit by way of commencement being 100,000 dollars; and on the deposit of securities to this amount, he may issue notes to the same value. It is a matter of complaint with the government of the United States, that many of the State governments should have taken up the policy of encouraging the issue of small notes by sanctioning the establishment of the banks of the class we have just described with deposits of mortgages, stocks, &c., on which the notes issue, and it is observed by the Treasury Department, that though these as an ultimate security, may be of some avail to the broker who buys them at a discount, and can afford to hold them for months or years until they resume their value in the market, yet the labouring man who has these State security bank notes in his possession when they stop payment, is apt to find that the ultimate security for the redemption of the promises to pay on demand "does not prevent his losing 25 cents, 50 cents, or even 75 cents in the dollar." In the State of New York, in 1856, the securities held by the Government Superintendent of Banking amounted to a value of 39,359,071 dollars. In that year the securities for six banks of the State of New York, which had stopped in 1855 were realised; but the produce in no case sufficed to pay the notes in full, whilst a period of from two to four years would have to elapse before the affairs of these banks could be finally wound up and settled.

In 1857, *all* the banks in the Union again stopped payment. In New York State the discounts of the banks had risen to 122,077,252 dollars, against deposits to 94,436,417 dollars in their possession. This maximum of both was reached on the 8th of August. On the 24th, the Ohio Life and Trust Company, great bankers in the city of New York, stopped payment, and so caused much distrust to spread abroad; the failure of other banks followed, increasing the panic till it rose to a run upon the banks; not so much, however, to get cash for the notes as for the deposits. To meet this state of things, the banks so reduced their discounts and advances, that on the 17th of October, they had fallen to 97,245,826 dollars, the sudden contraction of accommodation causing the fall of many merchants who had depended on the banks for supplies of money upon discounts, &c. The drain of deposits however still proceeded. The deposits on that day were only 52,894,623 dollars, a decrease of 41,546,784 dollars in nine weeks. The banks are said to have been guilty of improvidence in advances, partly in the injudicious manner in which they had allowed too high a rate of interest upon sums deposited on current accounts or at call, which is said to have caused the bankers in the Western States and others to keep large balances at New York. The effect of this was to tempt, and indeed force, the New York bankers to make advances on questionable security, in order to make a profit on the large sums lodged with them. A tendency to panics is said to be a feature of the American system of banking, and one reason assigned is the small quantity of coin with which American bankers in general carry on their business. This does not relate to the banks of the city of New York, where the action of the foreign exchanges compels them to keep up a stock of specie. In 1857, the 56 banks of that city had 8 million of dollars of notes in circulation, and 12 million dollars of cash in their coffers; but the 255 country banks of that State are returned as having 24 million dollars of notes in circulation, and 1,200,000 dollars only in specie. In 1856, in Massachusetts there were no fewer than 135 banks (exclusive of Boston), with 6,601,130 dollars deposits; circulation 13,106,068 dollars; specie in tills only 1,092,463 dollars. In Illinois, in 1857, the State Bank had out notes to 725,000 dollars, and 61,000 dollars in the till. The Graville Bank was circulating notes to the value of 471,556 dollars, and had 18,951 dollars in coin to support that immense currency upon. Other banks of that State had considerable circulations abroad, *with nothing* but their credit to rest on. In fact, the present American system is condemned by the voice of their own general government; the President having observed, in his Message to Congress of December, 1857, that the obligation of the banks holding an amount of United States, or State securities, equal to their circulation, furnishes no adequate security: "However valuable these securities may be in themselves, they cannot be converted into gold and silver at the moment of pressure, as our experience teaches, in sufficient time to prevent bank suspensions, and the depreciation of bank notes." It has been suggested that the returns made to the American government by the banks are not always deserving of full credit, a suggestion of great importance to be borne in mind by capitalists in this country, where American securities were supposed at this time to be held to 80,000,000*l.* value. We will conclude this part of the subject by the mention of a feature in the American crisis of 1857, which appears to possess much significance. In the State of New York all the banks, with the exception of the old incorporated banks already mentioned, are obliged to deposit State stock against every promissory note which they issue, and any bank which wishes to increase its issue, must, before it can do so, lodge with the Superintendent of the Banking Department an additional amount of State stock to the value of the contemplated issue. Accounts of all the transactions of these banks are published weekly by the Banking Department of the State, from returns made by the banks; within the two or three years previous to the crisis, the amount of subscriptions to the banks, and also the amount of deposits, had greatly increased, indicating increasing confidence in the stability of these establishments. But what showed in a still more remarkable manner the confidence was this, after the suspension of the banks, there having been a partial run for gold for their notes before the suspension, the notes continued to be taken and received, and to pass from hand to hand in the business of life, at little or no discount; though a person having a bank note which he wished to get gold in exchange for, could only obtain it upon a payment of one per cent. for the accommodation, which, of course, was given him by private individuals and not by the bank, and which per centage, therefore seems to mark the lowest degree in which the notes were depreciated. It should be mentioned also, that by a provision in the law of that State, the noteholder of a bank has a prior claim on the assets above all other creditors whatever, independently of the government securities deposited. The same thing took place, it appears, in most of the other States of the Union: after the suspension of cash payments by banks, the notes still continued in circulation, passing freely at little or no discount when they were notes issued on the deposit of an equal amount of State securities or of bullion. These banks are called Subscription Banks, from the mode in which they usually originate. The promoters of a scheme for a bank, put out a list of supporters, with the amount of capital intended to be raised. The list is exposed in the Stock Exchanges, and is filled up with the names of persons willing to take shares, until the full amount is subscribed. It is understood that in all cases the liability of the shareholders is limited to the extent (it seems) of the subscriptions or shares of each. The management is in the general form of a chairman, a cashier or secretary, and twelve directors. The number of shareholders is unlimited, and before they can commence business, all the shares must be paid up in full. In New York the usury laws prevent a higher rate of interest than 7 per cent. In other States there are also usury laws, under which various rates are enforced. (See 'Report of Committee of House of Commons on Bank Acts, &c.' 1858.) The history of the crisis seems to be deserving of study; it presents curious phenomena, both with respect to the confidence displayed by the noteholders, and still more by the depositors; in some instances, depositors were known to have returned the day after the suspension, and replaced their deposits in the very banks from which a day or two before they had withdrawn them; and in general, the banks of America, notwithstanding their frequent insolvencies, hold large amounts of deposits.

Banks of India.—Banking, as conducted by natives in the interior of India, is chiefly confined to the issuing and discounting of bills of exchange. These native bankers are called Shroffs, and the bills in which they deal are called Hoondees. They do not issue promissory notes payable to bearer. There is a very considerable circulation of hoondees, the interior inland business being principally conducted by their means. The great banking-houses at Benares have branches of their establishments in almost all the principal cities of Hindostan; by their means remittances from one part of the country to another are greatly facilitated. Europeans have not yet undertaken this branch of business, except at Calcutta and Madras. An attempt was made some years ago, by an English house in Calcutta, to establish a bank at Bhauleah, but without success.

There were at one time four private banks in Calcutta managed by Europeans; but two of them have ceased to operate. Only one of these banks issues notes: its circulation was at one time between 40,000*l.* and 50,000*l.*, but its issues have lately been much contracted.

A government bank, under the title of the Bank of Bengal, was opened in 1809. Its capital is 500,000*l.*, one-fifth of which was subscribed by the East India Company. This bank is said to have proved a great convenience to the community and the Bengal government, especially in Calcutta, where its notes chiefly circulate. This establishment receives deposits, discounts bills, and effects remittances to and from country districts, as well as issues its own notes: the amount of its paper in circulation is about 800,000*l.*, in notes varying in amount from ten rupees to 20,000 (1*l.* to 2000*l.*); the largest part is in notes of 100 rupees and upwards. In 1823 the bank obtained a new charter for five years, but exists now under the sufferance of the government. The management is vested in nine directors, three of whom are nominated by the Indian government. The president is chosen from among their own body by the directors. Natives are eligible to become directors, none of whom are paid for their services. A statement of its affairs is submitted twice in each year to the proprietors, and sent to the government. This bank has at times lost considerably through having advanced money on forged documents to natives, who are great adepts at this kind of dishonesty. Although thus closely connected with the government, the bank does not transact its money business. The government keeps its own treasury quite distinct, but frequently holds a considerable sum in the notes of the bank. The average dividend made to the proprietors has been from nine to ten per cent.: the stock bears a high premium.

There is a bank at Madras which is altogether a government concern. It receives deposits, discounts bills, and issues notes which have no circulation beyond the limits of the city of Madras. It yields an annual profit of about 10,000*l.* to the East India Company.

The Bank of Bombay divided, for the half-year ending 31st Dec., 1858, of rupees forty-five per share, being at the rate of nine per cent. per annum on the capital stock of the bank.

Colonial Banks.—In several (not all) of the British colonies the banks pay interest on the deposits made by their customers. The practice has been discontinued in New South Wales, as far as accounts current are concerned; it has never been in operation in Tasmania, and has not yet (1859) been carried into effect in South Australia.

The Bank of Australia was established in 1835. Since 1841, the capital (which was enlarged in that year) has been 900,000*l.*, on which the dividend of 20*l.* per cent. per annum is now paid.

The Bank of New South Wales paid, for the half year ending 30th Sept., 1858, at the rate of 20*l.* per cent. per annum: this was the sixteenth half-yearly meeting of the company.

The Colonial Bank (established twenty-two years) divided last year at the rate of eight per cent. per annum, on a paid-up capital of 500,000*l.*

The Union Bank of Australia, for the year ending 31st Dec., 1858, divided at the rate of ten per cent. per annum on a paid-up capital of 920,000*l.*

Most of these, as well as various other banks whose business lies chiefly in the colonies, are managed by boards of directors sitting in London. For particulars respecting the law as relates to them, see Grant's 'Law of Bankers.'

II. *Objects and General Principles of Banking.*—From what we have already stated, it will be seen that banking establishments are undertaken with very different objects, and are prosecuted by very different methods. The whole may be divided into three classes, namely, banks of deposit, banks of issue, and banks which exercise both these functions.

Banks of deposit, strictly speaking, are those which, like the old Bank of Amsterdam, simply receive the money or valuables of others into custody, and keep them hoarded in their coffers till called for by the depositors. However convenient such an establishment may be to the persons by whom it is used, it must be evident that it can contribute nothing to the general wealth of a community, and that the only means of profit which it provides for those who conduct it, must arise from payments made by its customers in the shape of commissions, or fines which partake of the nature of commissions. If, instead of burying the clipped and worn coins of which its hoards were composed, the Bank of Amsterdam had converted them into money of the proper standard, and had lent the same at interest upon proper securities, no commissions need have been required from its customers, who would in so far have been benefited; and a considerable capital being set free for the prosecution of commercial enterprises, the country might have thence derived continued additions to its wealth.

Banks of deposit, in this confined sense of the word, are now very little used; and the term is generally understood to mean an establishment which *lends* as well as *takes* the property of others, and derives its profits from charging a higher rate of interest than it allows. Some banks of this description, such as most of the private banks in London, do not allow any interest upon sums placed in their custody.

In like manner there are few, if any, establishments which are purely banks of issue. A banker sends forth his promissory notes, after incurring the necessary expenses, that he may employ to his own profit, during the time that the notes remain in circulation, the money or property for which he may have exchanged them, and by this course he gives to his establishment the mixed character of a bank of issue and of circulation. The expression, bank of circulation, is frequently understood to signify a concern which issues its own notes, but it seems better, for the sake of perspicuity, to draw the distinction here made. In general, those bankers who issue their own notes and circulate the money of others, which by that means comes into their possession, likewise receive deposits: this at least is the practice in this kingdom. In each of the cases described, with the exception of the first, the practice of which has become nearly obsolete, the object of the banker is to raise a borrowed capital, which he holds at call, and with which he supplies the wants of others who are willing to pay for its use.

Persons who follow this line of business, and more especially associations formed for the same purpose, usually possess considerable wealth, and are thought deserving of confidence on the part of the public; and there can be no doubt, that so long as they conduct their business with integrity and prudence, they are of material service in giving life and activity to commercial dealings. They are, in fact, the means of keeping that portion of the uninvested moneys of a country fully and constantly employed, which but for their agency would frequently lie dormant and unproductive for uncertain periods in the hands of individuals.

The relation of a banker to his customer is that of debtor and creditor: the customer's account consists in ordinary cases of money which he lends to the banker upon call, that is, demandable at any time, in whole or in part, by means of a cheque drawn by the customer and payable by the banker, at sight, whenever it is presented to him within the banking hours of his establishment. It is extremely important to bear in mind that in all cases of ordinary banking, where the customer has an account current with the banking house, the obligation under which the banker lies is to pay his customer's cheques at all times within his usual banking hours, to the full extent of the amount of the customer's credit account at the time that each cheque is presented for payment. For the more fully effecting this object, the law looks upon the banker as bound to know what is his customer's hand-writing, and what writing is not his: so that if the banker should negligently cash a cheque purporting to be signed by a customer, the customer's signature being in fact forged, the banker must bear the loss, and not the customer. Also, if the banker should negligently refuse to pay a customer's cheque, thinking that the customer had at the time of presentation no funds in his (the banker's) hands, and it turns out that the customer in truth had funds at the time in the banker's hands to the amount of the cheque, the banker is liable to an action at the suit of the customer, although the latter may not be able to show that he has suffered any real loss from the refusal to cash his cheque. Such cases depend on the leading rule which governs the settlement of most of the questions that arise between bankers and their customers, and which is simply this: When a loss arises, and it is found that one of two innocent parties must suffer the loss, it is to fall upon that one of the two whose conduct led the way and opened the door to the fraud which caused the loss to be effectuated.

A banker's business consists in borrowing the money of some in order to lend to others. In banking conducted on pure principles, the banker's capital is not used for the purpose of profit in the same way in which he uses a part of the moneys that his customers deposit with him; his capital ought to be invested in government securities, yielding him 3 per cent. per annum interest, which securities he can readily convert into money in case of an unexpected demand upon him by his customers, for the return of the sums they have left in his keeping. Their deposits, for the larger part, he employs in such a manner as to derive interest from the loan of them to persons who are willing to pay for the use of the money thus advanced to them. The mode of doing this is usually by the discount of bills of exchange, not having long periods to run, and the amount of which the banker receives from the acceptor of each bill when it has arrived at maturity. The rest of the deposits made by his customers in ordinary times, to the extent of one-third or one-fourth of the whole sum deposited by all his customers, he keeps in cash in his till, to meet the daily claims made upon him by his customers by cheques. This, in ordinary times, is found to be sufficient, because in such times the payments out and the receipts are found nearly to balance every day.

A banking business consists therefore in dealing in money and credits, and in order that his credit may never for an instant become impaired, he will always have a sufficient capital as a reserve, which, being invested as above-mentioned, he can always be able to realise at a short notice, when a season of pressure or mercantile crisis renders it apparent, that demands are coming upon him more rapidly than he shall be able to meet, by withdrawing the moneys of his customers that he is making use of, and profit by, in the way of loans. The influence upon the public as affecting their opinion of the stability of the bank, arising from their having a superabundant capital, is immense. The best and safest mode of employing the funds deposited with the banker is considered to be, by the highest authorities on this subject, the discount of good mercantile bills of exchange, that is, bills which represent *bonâ fide* transactions of trade and commerce. Advances are also sometimes made by bankers on the deposit of Exchequer bills, or other government securities, or railway debentures, and sometimes on goods, produce, or dock warrants; but these last three descriptions of securities are not considered to be of the most eligible class, because they are attended with more risk, trouble, and delay in converting them into money. Mortgages on land are, for similar reasons, also regarded as securities which it is unwise in a banker to invest his customer's money largely in; but it is not meant to lay this down as an invariable rule. In a large business, where experience shows that, in ordinary times, but a small proportion of the whole amounts deposited is necessary to be retained in the shape of cash in the till—that is, Bank of England notes, gold, silver and copper coins—to meet the average daily outgoings, it may not be altogether objectionable that investments, to some extent, should be made in mortgages on land: the extent to which this should be done being matter for the discretion and judgment of the banker, founded upon his knowledge of the character of the borrower, the value of the land, whether it is already under mortgage to any extent, and other considerations, of various kinds, depending on the nature of each transaction.

The qualities, therefore, which are required to be possessed by every banker, are prudence, caution, vigilance, assiduity, together with knowledge of the character and dealings, and the particular descriptions of business, of the persons to whom he advances loans. Besides this, dealing in credits as he does, the most scrupulous integrity and fairness is exacted from him by the law. "It appears to be assumed, that a failure of a banker *is by itself* evidence that he has been acting dishonestly. The customers of a banker have a right to look to him for the exercise of cautiousness and circumspection, for undeviating adherence to the purest good faith and strictest integrity, in the use of their money which they have lent him as a banker; they have a right to expect that he will confine his trade to its legitimate field, namely, of discounting bills, and of purchasing, or advancing money upon, proper securities." (Grant's 'Law relating to Bankers and Banking,' pp. 315, 316.)

Hence all engaging in pursuits of a speculative character, such as mining, is invariably declined by prudent bankers. A very large proportion of the failures that have taken place in banking concerns, are traceable to errors of this description. Banks, in the commencement perfectly sound, have often sunk from the results of having been led on in such business as the following:—A customer manufacturing largely applies for an advance, offering a mortgage of landed property on advantageous terms as security; the advance is made, but after a time the customer returns representing that he has made bad debts which cannot at present be realised, and that he is in want of cash to carry on his concerns, and that if he is not accommodated the result will be that he must stop, in which case, in the present posture of affairs, the banker will in all probability be a loser. The banker, therefore, consents to a further loan, taking perhaps as security a bill of sale of the manufacturer's plant and machinery. Such cases too frequently end in the banker suffering great loss, which becomes known; his credit is accordingly impaired, the customers become alarmed for the safety of their deposits, a run upon the bank ensues, and it is obliged to stop payment, and the end is bankruptcy and ruin. Then in cases of bankruptcy, the disclosure of reckless dealings of this nature, or other misconduct, such as allowing a partner greatly to overdraw his private account with the bank, without exacting from him proper security; permitting unnecessary litigation, wrongful dealings by way of transfer, pledge, or any kind of conversion, with a customer's securities that may have been lodged at the bank for safe custody; failure to keep proper books, ignorance of what the books show to be the real state of the bank; are all matters which press sorely against the bankrupt, and some of them may be made the grounds of criminal proceedings, and lead to severe punishments.

Private bankers (meaning thereby firms formed by voluntary association, in distinction from the bodies formed under the statutes regulating banking co-partnerships and joint-stock banking companies respectively) do not, in general, allow interest to their customers on the sums lodged with them, as the last-mentioned bodies are almost universally in the habit of doing throughout the United Kingdom. Public banks are those which are established under the statutes above referred to, and hereafter to be more fully explained. They are for the most part bound to make periodical statements to their shareholders: in effect, to publish such statements as the legislature has thought to be adapted to disclose the real condition of the banks, and the actual mode in which they are doing business; but the history of banking shows, that whilst most of these concerns are prosperous and enjoying most extensively the confidence of the public, no device that has yet been discovered can guard either customers or shareholders from the ruin that has occasionally been caused by the mismanagement, either through ignorance and incompetency, or from a fraudulent disregard to their duties, of those who have the direction of the affairs of a bank. The disasters which have arisen from the insolvency of large joint-stock banks have not arisen from any inherent vice in the system itself, nor from any inaptness of the joint-stock principle for dealing with banking concerns, but from the criminal want of integrity of those who guided the affairs of the establishments which have fallen. The joint-stock banks are in general willing to receive smaller sums, by way of opening accounts with customers, than private bankers; in many cases as low as 10*l.*, and this circumstance, together with the attraction of the interest which they very generally allow on their deposits, and the confidence which the public place in the great number of persons who hold shares in each bank of this description, liable to the whole extent of their fortunes for the debts of the concern, have led to vast increase in the sums deposited with this class of bankers within the last ten or twelve years, so that the lowest estimate which is made by good authority, of the aggregate amount of money held in deposits in the various banks of the United Kingdom, reckons it at 500,000,000*l.* sterling.

One of the great benefits which is produced by a widely spread system of banking lies in this, that it provides the means by which the surplus capital of one part of the country is transferred to another part where it is wanted, and where its use is of the highest value in increasing the activity of trade, and giving employment to industry. Thus the agricultural districts affording but little opportunity for the employment of money, bankers in business there, finding no means of employing their deposits in the discounting of local bills of exchange, or in loans on other eligible securities, are in the habit of sending to their agents in London such sums as they can spare with due regard to the requirements of their tills. On the other hand, in the great centres of commercial and manufacturing activity, of the cotton, woollen, and iron trades, and in the mining districts, the merchants are in the habit of drawing bills of exchange in payment for the goods they have sold to their customers, and a large proportion of these bills come up to London to be discounted, which is done with the money above mentioned as having been sent up from agricultural localities, and with the deposits in the hands of the London joint-stock banks, which are chiefly made by the small traders of the metropolis, and by widows, servants, mechanics, artisans, &c. It is in this way that banks aid the rapid and continual circulation of money between parts of the country where it is not wanted for immediate use, and parts of the country where the demand for its immediate use is pressing and urgent. Another mode in which the utility of banks, and the general diffusion of the habit of keeping accounts with bankers instead of hoarding money at home, is displayed, is this: If every payment were required to be made in coin or Bank of England notes (which, since 1844, are a legal tender everywhere except at the Bank of England, as will be more fully explained hereafter), the expense and trouble, and risks attending on such a system would be incalculable. Banking to a very great extent prevents the necessity of this, and therefore effects a great economy as regards the currency or necessary supply of the circulating medium. [CURRENCY.] A customer of a bank, when he has a payment to make, instead of taking the necessary amount in coin or Bank of England notes out of his strong box, simply writes a cheque or order upon his banker desiring him to pay the creditor the required amount. This the creditor presents to the banker, and if the creditor has an account with his house, the banker may satisfy the cheque by transferring in his book the specified sum from the account of the debtor to the account of the creditor, and so it will not be necessary that any money should pass in the transaction. But if the creditor, or payee of the cheque, has not an account with the same banker, it may, it is true, be necessary that the cheque should be cashed, by handing the specified sum over the counter to the payee. In London, however, the great centre of the money transactions of the realm, even in this case, by means of the institution of the Clearing House (which will be explained in detail hereafter) the system of cheques has the effect of causing immense savings of expense and trouble as regards the circulation. The effect, upon the whole, in this direction of the great development which has taken place of late years in the practice of using bankers throughout the kingdom, is seen in the following statement contained in the Report of the Select Committee of the House of Commons on the Bank Acts, which sat in the session of 1858:—"While, on the one hand, the great increase of retail transactions has caused an increased demand for the smaller notes (of the Bank of England) concurrently with the increased demand for gold, yet, on the other hand, so great has been the effect of increased facilities in banking, that a saving of a corresponding amount has been effected in the larger notes. The effect has been so great, that notwithstanding the great increase of trade, the whole amount of Bank of England notes has actually diminished since 1844, and under the present law still continues gradually to decline."

With regard to the notes of the private banks of issue, it is manifest, at first sight, that a large portion of their profits must be derived from the interest which they make upon the money which these notes represent; for, suppose a private banker to issue a note for 1000*l.*, he only parts with it to some one from whom he has obtained a security for its repayment, with interest. The banker has therefore exchanged his promise to pay 1000*l.* on demand for an obligation of equal amount, bearing the current rate of interest: therefore, so long as the note, the intrinsic value of which does not exceed sixpence, remains in circulation,—that is, until it is presented for payment,—and the banker is obliged to pay the 1000*l.* in return for it, he will, supposing the interest he makes to be five per cent., have derived an income of 50*l.* from the note. Or, to put the case in another point of view: a customer asks for a loan of 1000*l.* upon a deposit of railway debentures or consols; the banker makes the loan by handing over the counter one of his own notes for 1000*l.*, and if the debt is not repaid according to the terms of the agreement, he may sell the securities and place the proceeds out at interest, which interest, whatever it be, is in fact the interest of his note, because he has never disbursed anything. No money has as yet passed out of his coffers; he has coined, as it were, a prospective liability; and, until the note is returned upon him, with a demand to be paid in gold or Bank notes, or credited in account, he enjoys the interest upon it. This view however does not appear to be coincident with that which private bankers, who issue notes, in general entertain of the value to them of their note circulation; for it was alleged before the above-mentioned committee, by various witnesses connected with private banking, to be the opinion generally entertained among them, that if they were obliged, according to a proposal that has often been suggested, to make a deposit with government of consols to the amount of their issues, they would prefer to sacrifice the issues altogether.

The most scrupulous attention to correctness and integrity, and fidelity to the interests of those who confide in him, have been partially shown to be the duty of a banker; but it may be necessary still further to elucidate this subject by showing some of the consequences which may follow even slight departures from correctness, and, though no moral guilt be incurred, may nevertheless press most heavily on the offender or on his family. The books of a banker are always kept on the principle of perfect correctness; that an alteration shall never be needed; that from first to last they shall show clearly and incontestably that which they are kept to show,—namely, the state of the affairs of the bank down to the minutest particular. The banker is held to be under the obligation of knowing what is in his books; he cannot, for instance, escape from the consequences of making or joining in a representation of the affairs of the bank different from that which the facts authorise, by alleging that he was not in the habit of looking into the books, and did not know that what he stated or sanctioned was untrue. It is his duty—a duty that the law does not allow him to shake off—to be aware of the position in which the bank stands before he undertakes to make statements respecting that position, by relying on which, other persons may suffer. The following example will render more clear what has been said: In the city of W. a bank had been established for many years. It had acquired considerable provincial celebrity, and was said to have enriched more than one of those who had been partners in it. In 1850 the then partners, A. and B., took into partnership C., who was to have one-third share of the profits and assets. A. was not an active partner, though he sometimes attended at the banking-house, without however seeing customers or taking any ostensible part in the management or conduct of the business. B. was a practising solicitor, who nevertheless attended closely to the business of the bank. C. was a retired solicitor: he paid a sum of money upon being admitted a partner to the business, the nature and liabilities relating to which, it turned out, had been grossly misrepresented to him by A. and B. But for these misrepresentations he would not have become a partner. The courts of equity held that, notwithstanding it was clear that A. knew nothing of any fraud in the representation of the state of the concern which he made, being himself totally in the dark, and having relied entirely on a confidential clerk (subsequently discovered to have been engaged in a long course of dishonesty and fraud), and therefore that he was to be entirely acquitted of any moral culpability; yet, being bound to know the truth of what he advanced, in such a case, he was as much personally liable to C. as if he had known the falsehood of what he asserted,—that is to say, he was liable to indemnify C. from the loss which he had suffered, or to put him into the same position as if he had never entered into the partnership. B., the other partner, knowing the real state of affairs at the time the misrepresentation was made, was of course liable to the same extent.

A bank is very commonly used by customers as a place of security to deposit plate, jewels, government and other securities, title-deeds, &c., for safe custody; and the banker frequently manages the customer's public stock for him, receives the dividends, and sells out or buys in according to his directions, and in the case of selling it is necessary for the banker to have a power of attorney from the customer to enable him to effect the sale. Now, in any of these cases any malversation on the banker's part is severely punished. If, being in charge of goods, &c., for safe custody, he sells or pawns the goods, or negotiates the securities, or pledges them, or deals with either in any way with a fraudulent intent, or if, having a power of attorney, he fraudulently uses it for his own purposes, he is in any of these cases punishable as for a misdemeanour (20 & 21 Vict. c. 54); and the reason why a banker is held by the law up to so rigid a standard of correctness, and why he is so severely punished in case of departure from it, is that complete confidence is the essence of his vocation,—he deals not with his own but other people's property; the consequences of a departure on his part from the rules which experience has shown to be indispensable, are incomparably more grave in the misery, and distress, and ruin which it causes, than in cases of ordinary offenders against the law. Then he has not a valid excuse in ignorance. Bankers, it is said, are in possession of peculiar means by which to become acquainted with the position, the character, and capacities of those who deal with them; and it is their duty to employ all those resources to distinguish between the applicants for accommodation who can bring security in one of the best forms, namely, that of their character, energy, and prudence, and the reckless and improvident trader. Provided they make reasonable inquiry, it is not probable that they will often be deceived in their judgment of individuals in this respect; and provided they act with caution, it is impossible that they can ever suffer themselves to be so far involved, even with the most respectable customer or firm of customers, as to be themselves injured in case of failure of the latter.

It perhaps may be difficult to form an estimate of the amount of money held as deposits by bankers in the United Kingdom; very high authorities estimate it at an enormous number of millions sterling, and have considered that probably 500 millions sterling is not much above the proper mark, of which probably one-half is payable at call. This gives some idea of the vastness of the trust which the community repose in the banking body, especially when we consider that this enormous sum is lent to them without security; and, indeed, the growing practice of opening accounts with bankers—in other words, lending to bankers so much money to be returned on demand—has been looked on by some as a most embarrassing question, owing to the difficulty of deciding whether the evils inherent in the system do not countervail the advantages; and considering it on the whole, as at present conducted, to bear the character of a formidable evil, the remedy suggested has been to enact that all sums bearing interest, lodged with bankers, brokers, &c., should not be demandable without a month's or six weeks' notice; and it is alleged that a regulation of this sort would not interfere with anything that is valuable in the existing system, while it would confer on it some portion of that solidity of which it is at present so miserably deficient. It would protect all classes against the effects of sudden and unreasonable fears and panics: it would give time to the borrowers to collect their resources, and to the depositors calmly to inquire into the character and situation of those to whom they had intrusted their money.

III. *History and Constitution of the Bank of England.*—This establishment, unquestionably the largest of its kind in the world, was projected by a Scotch gentleman, Mr. William Patterson, in 1694. The scheme having received the sanction and support of the government, to whom the whole of the capital was to be lent, the subscription was filled in ten days from its being first opened. The government being at the time much embarrassed for want of money, partly from the abuses of taxation and the defective modes of impost that were prevalent in those days, and partly from the difficulty of borrowing, owing to the feeling of insecurity and the want of confidence in the stability of the revolutionary establishment, the Bank arose out of a loan of 1,200,000*l.* for the public service. The government paying to the subscribers 8 per cent. on the sum advanced, and 4000*l.* a year for management, or 100,000*l.* a-year in all, agreed to incorporate them by the name of the Governor and Company of the Bank of England. The charter was granted to continue (by virtue of an Act of Parliament of that year) for eleven years certain, or till a year's notice after August 1, 1705.

Under the auspices of the then chancellor of the exchequer, Montague, a complete re-coinage of the circulating medium had taken place in 1696; and in the course of this year the Bank fell into great difficulties, and, in fact, was compelled to suspend payment of its notes, which had fallen to a heavy discount. By means, however, of the prudent course adopted by the directors, and by aid from the government, the Bank contrived to weather the storm; but it was determined to increase the capital from 1,200,000*l.* to 2,201,171*l.*, which was accordingly done.

In 1708, the Bank undertook to pay off and cancel 1½ million of Exchequer Bills, which they had circulated two years before at 4½ per cent., with the interest upon them—in all 1,775,028*l.*; so increasing the permanent debt due from the public to the Bank (including 400,000*l.* then advanced as payment for the renewal of the charter) to 3,375,028*l.*, on which they were to be allowed 6 per cent. The Bank capital was also then doubled; that is, it became 4,402,343*l.* It was in this year also that the Bank obtained the famous provision to the effect that, during the continuance of the corporation of the Bank of England, no partnership or body consisting of more than six persons should "borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in any less time than six months from the borrowing thereof," and the exclusive privileges were continued till 1733; and they have since been prolonged to the 1st August, 1855, with the proviso that they may be withdrawn on a year's notice to that effect being given to the Bank by the House of Commons, through the Speaker, after the 1st August, 1855.

In 1727, we find that the capital had increased to nearly 9,000,000*l.*

In 1746 it was 10,780,000*l.*

In 1782 it was increased by 8 per cent., or became 11,642,400*l.*

In 1816 it was raised to 14,553,000*l.*, at which it at present stands.

The Bank of England, as is well known, has had to struggle with severe pressure at particular periods of panic, as they are called. We cannot, consistently with the proper limits of this article, do more than refer to the most striking of them. The first of these was that of 1745—the Black Friday, as the day was long called in the City—when, news having arrived that the Pretender had advanced to Derby with his Highlanders, a run upon the Bank by the holders of its notes took place, which it is said the directors succeeded for the time in staving off by the device of paying each note in shillings and sixpences. They received more solid advantage from the effect of a resolution which was very numerously signed at a meeting of the merchants of London, that they would receive the notes of the Bank of England to any amount in payment of debts due to them, &c.; on which, and on the arrival of information of the retreat of the rebellious army, confidence returned.

In 1796, and the early part of 1797, there had been confident assertions of the intention of France to invade this country, and runs had taken place in consequence on many of the provincial banks, until the panic spreading, extended itself, as always takes place in such cases, to London, and the demands for cash on the Bank of England multiplied so fast, and to such an extent, that on Feb. 25, 1797, only 1,272,000*l.* of cash and bullion remained in its vaults. This was Saturday, and there was no prospect or hope that the run would have subsided on Monday. This being the state of things, an order in council was issued on Sunday, prohibiting the directors from paying their notes in cash until the sense of Parliament could be taken. The result of the discussions in Parliament was, that it was agreed that this restriction should continue until six months after the signature of a definitive treaty of peace, and an Act of Parliament was passed accordingly. The apprehensions which the order in council of restriction had caused were again allayed by a meeting of principal merchants, agreeing to accept and use every means to induce others to accept, Bank notes as money in all transactions. A committee of Parliament, which investigated the subject, reported that, at the moment of issuing the order in council, the Bank was possessed of property to the extent of 15,513,690*l.* after all claims had been satisfied. Bank of England notes were not, it is to be observed, expressly declared to be legal tenders; but they were in effect made so. In 1801-3 their issues are stated to have been so much increased that the notes fell to a discount of as much as from 8 to 10 per cent. In 1804 the notes recovered their ostensible value, but from that time to 1808 they were again at a discount of 2½ per cent.

Hitherto the issues had not exceeded 17½ millions sterling or fallen lower than 16½ millions, in any one year from 1802 to 1808; but in 1809 they became 18,927,833*l.*, and in 1810 reached 22,541,523*l.* The issues of country bank paper were also much enlarged, without, as it appears, there having been any adequate increase of business or activity of demand for money in the community to make such steps justifiable; the consequence was, that Bank notes in 1809 and 1810 were at a discount of from 13 to 16 per cent. Hence arose a corresponding fall in the foreign exchanges; and the matter seemed deserving of the attention of the legislature, so far as that a committee of the House of Commons being appointed in the latter year, recommended an early return to specie payments; but this recommendation not being acted on, the notes of the Bank were at an average discount in 1812 of 20¾ per cent. as compared with bullion; in 1813, of 23 per cent.; in 1814, of 25 per cent. The mode by which they regained by 1816 nearly a par with gold, was the following: In 1797, at the period of the restriction, it had been supposed that there were about 280 country banks in operation; but in 1813 these had increased to upwards of 900. Wheat had been unusually high during the five years ending with that year, but the harvest of that year turning out to be above an average one, and the continent being again opened to British commerce, a heavy fall took place in prices at the end of 1813 and the beginning of 1814. This having brought many farmers into insolvency, caused a want of confidence in the rural districts; and it is said that, in 1814, 1815, 1816, no fewer than 240 country banks stopped payment, and 89 commissions of bankruptcy were issued against bankers. Hence the field for the circulation of Bank of

England notes was necessarily much increased, as the void in the currency caused by the destruction of so many banks of issue (there being at that time no legislative restraint upon the establishment of a bank of issue except what has been mentioned) must needs be filled up, and the value of the note was in 1816 raised nearly to a par with gold. This facilitating very much the return to cash payments, by Mr. Peel's Act of 1819 (59 Geo. III. c. 78) it was fixed that the resumption should be made in 1823; in the interval the Bank was to pay its notes, if required, in bars of standard bullion of not less than 60 ounces weight. However, a large amount of gold having been accumulated in the Bank vaults, the directors recommenced specie payments on May 1, 1821. As regards the practical operation of this Act on the currency much speculation and discussion has taken place, into which we cannot here enter. [CURRENCY.]

In the latter end of December, 1825, occurred that collapse of credit and confidence which is known as the panic of 1825, in the course of which the pressure upon the Bank for cash for the country banks was so great that the gold in its vaults was reduced extremely low; insomuch that, but for the fortunate discovery of an old box containing a quantity of one pound notes which had been overlooked, and which were now brought out and issued, to the amount of one million, in payments, the Bank must, according to the evidence of one of the directors before a committee of the House of Commons, have suspended payment. The Bank directors appear on this occasion to have applied to the government for an order in council restraining payments in gold; but this the government, throughout the period of pressure, steadily refused to grant.

This crisis was owing chiefly to the immense number of speculative schemes which had been set on foot in the course of the year 1824. From a published table of these, we find the total amount proposed to have been subscribed for these schemes (or bubbles, as many of them were) was 248,000,000*l.*; that the amount actually paid up was 43,062,608*l.*; and that the balance due on the whole, at the end of 1825, was 204,937,392*l.*

In 1826 the Act of 1708 was partially repealed, so as to admit of the formation of banking copartnerships for the issue of notes with more than six partners, at any distance exceeding 65 miles from London; but these establishments were restrained from having any branches in London; and it was expressly declared that the partners, jointly and severally, should be held liable for all the debts of the bank with which they might be connected.

On the other hand, the Bank of England had the privilege given them of establishing branch banks in the provinces. This was viewed with such alarm by the country bankers, who saw in it "the object of supplanting the existing banking establishments, and thereby rendering the Bank of England masters of the circulation of the country;" but these apprehensions have not been borne out by the results. In some places where the Bank had established branches, the experiment has failed, and the branches have been discontinued; and it is doubted whether, upon the whole, the business done at those establishments has been a source of much advantage to the Bank. The present number is believed to be eleven. An agent or manager is placed in charge of each branch, which is visited at uncertain periods by an inspector. The agents at all the branches communicate daily with the Bank of England, advising every transaction which has been entered into during the previous day, the total amount of moneys paid out, the total amount received, the total amount of the bills discounted, the total cash balances remaining, the notes received and cancelled, &c. In places where branch banks are established, revenue payments are made through them. They also receive many dividends that were formerly received by the provincial banks.

In 1833 considerable alterations were made in regard to the relations of the Bank to the public by 3 & 4 Will. IV. c. 98, by which it was provided that no association, having more than six partners, shall issue bills or notes payable on demand in London, or within 65 miles of that city, during the continuance of the exclusive privileges granted to the Governor and Company of the Bank of England. But associations, "although consisting of more than six persons, may carry on the trade or business of banking in London, or within 65 miles thereof, provided they do not borrow, owe, or take up in England any sum of money upon their bills or notes payable on demand, or at any less time than six months from the borrowing thereof, during the continuance of the privileges granted by this Act to the Governor and Company of the Bank of England."

All promissory notes of the Bank of England, payable on demand, issued at any place in England, out of London, where the business of banking shall be carried on for or on behalf of the Bank, must be made payable at the place where such notes are issued; and it is made unlawful for the Governor and Company of the Bank of England, or for any person on their behalf, to issue, at any place out of London, any promissory note payable on demand, not made payable at the place where the same is issued.

Bank of England notes shall be a legal tender except at the Bank and its branches.

One-fourth part of the debt owing from the public to the Bank, amounting to 3,671,700*l.*, was to be paid back to the Bank. It was on this occasion proposed among the directors, that a sum equal to this sum should be distributed rateably to the proprietors of Bank stock, on the ground that the existing capital was amply sufficient to answer all the purposes of a banking capital.

In 1844 the enactment under which the Bank of England is still (1859) regulated was passed. Sir R. Peel, in introducing the measure to the House, explained the magnitude of the questions connected with banking and the currency, in these terms: "There is no contract, public or private; no engagement, national or individual, which is unaffected by it. The enterprises of commerce, the profits of trade, the arrangements to be made in all the domestic affairs of society, the wages of labour, the transactions of the highest amount and of the lowest; the payment of the national debt; the provisions of the national expenditure on the one hand, and the command which the coin of the smallest denomination has over the necessaries of life on the other, are all affected by the decision to which we may come on this great question."

The Act 7 & 8 Vict., c. 32, is intituled "An Act to regulate the issue of Bank Notes, and for giving the Governor and Company of the Bank of England certain privileges for a limited period;" and the most important enactments of it are those which provide for the issue of notes. This is to be carried on in a separate department from the banking department; and the issue department can only be carried on according to a system of rules and regulations prescribed in the Act. The issue department is constituted by transferring, appropriating, and setting apart to it, securities to the value of 14 millions, of which the debt due by the public to the Bank is to be deemed part, and also by transferring, appropriating, and setting apart to it, so much of the gold and silver bullion *then held* by the Bank as was not required by the banking department; and this being done, there was to be delivered out of the issue department such an amount of notes as, with those then in circulation, should be equal to the aggregate of the securities, coin, and bullion so transferred to the issue department. Then it was enacted, that "the whole amount of notes then in circulation, including those delivered to the banking department, should be deemed to be issued on the credit of the said securities, coin, and bullion." Also the Bank was prohibited from increasing the amount of securities for the time being in the issue department, except as will be mentioned presently; but permission was given to diminish the amount of such securities, and *again* to increase them to any sum not exceeding 14 millions, from time to time, as the Bank should see occasion. After the constitution of the issue department, the Bank was not to issue notes either into the banking department or to any person or persons whatsoever, save in exchange for other Bank of England notes or for gold coin, or for gold or silver bullion received or purchased for the issue department under the Act, or in exchange for securities acquired and taken in the issue department.

Under the banking department it was permitted that the Bank might issue all such notes as they should at any time receive from the issue department or otherwise, in the same manner as ordinary banks of issue. With regard to bullion they were limited to retain in the issue department, at any one time, an amount of silver bullion not exceeding one-fourth of the gold coin and bullion at that time held in the issue department; and all persons were to be entitled to demand from the issue department notes in exchange for gold bullion, at the rate of 3*l.* 17*s.* 9*d.* per ounce of gold of standard fineness, the gold to be melted and assayed, if necessary, at the expense of the party tendering it.

An increase of the security in the issue department was permitted to be made, in case any banker, who on May 6, 1844, was issuing his own notes, should cease to do so; then, on the application of the Bank, an order in council might authorise an increase of the securities beyond the 14 millions, and an issue of notes thereon to the extent of one-third of the private bank notes withdrawn from the circulation. Finally an account was to be published weekly, in a prescribed form, of the amount of notes issued by the issue department, and of the gold coin, and of gold and silver bullion respectively, and of securities in the issue department. Also an account of the capital stock, and the deposits, and of the money and securities belonging to the Bank in the banking department.

By these arrangements, the functions of the Bank with regard to the circulation were very materially remodelled; and under the operation of the Act it became, properly speaking, no longer a bank of issue, but in its issue department was made merely the agent to carry into effect the rules imposed by Parliament, without possessing any discretion or power of action of its own in the matter. An average amount of about 20 millions' worth of Bank of England notes appears at present to be permanently with the public for the purposes of circulation, and over this quantity of notes the Bank has no power, either to increase or diminish it; for if the Bank sells securities in order to draw in a portion of the notes out with the public, those securities would either be paid for by the withdrawal of deposits from the Bank, or by cheques, in which case no notes would pass at all; and if the Bank tried by any means to increase the number of notes in circulation, the surplus would immediately be returned in deposits: so, in either case, the total with the public remains unaltered.

The great object of these regulations was to place the convertibility of the Bank of England note into gold at all times on a secure basis, to cause the note circulation to fluctuate precisely in the manner that a purely metallic circulation would have fluctuated, and give the power to the Bank of England of acting upon the foreign exchanges when unfavourable to this country; and the Bank has been enabled, it is alleged, under the operation of the Act, to give much greater accommodation to the mercantile community, and also to various banks, by means of discounts and advances upon securities, in seasons of monetary crisis, than it could have done if it had been left without the support of the Act, in which case it must have regarded solely the security of its position as a mere banking establishment. The convertibility of the note is put beyond question, it will be observed; because it is hardly possible to conceive a drain upon the treasure in the Bank to be carried so far as to reduce the outstanding notes below 14,000,000*l*.

It may be well to mention here, that when the bullion in the Bank of England is spoken of, the bullion in the issue department is intended. When persons speak of the reserve of the Bank of England, the aggregate amount of the notes and coin in the banking department is intended. In ordinary times, the Bank thinks the right course is to keep a reserve to the amount of one-fourth of the deposits placed by bankers, merchants, traders, and private customers in their hands. It is the practice for the London banks, instead of keeping in their own tills the whole of the sums which they regard it to be right to have constantly under their control in order to meet the demands of their customers from day to day, to keep a portion of those sums in the Bank of England. The Bank also opens drawing accounts with merchants, traders, and others, upon which they draw cheques, and pay in such cheques as come into their hands, in the same way as in the case of an ordinary bank; and for persons keeping such drawing accounts the Bank discounts bills of exchange, provided they have on them the name of two or three persons of approved credit, and provided that in case any one of the persons whose names are on the bill fail before the bill has arrived at maturity, the Bank shall be entitled to demand and receive the amount of the bill from the person for whom it was discounted: this the Bank has no legal right to enforce, but in case compliance is refused, it closes that person's discount account, and declines to discount for him in future.

The deposits in the Bank consist of the government balances, which rise from small amounts at one period of the quarter, up to five or six millions higher at another period of the quarter, and then again subside to a low condition. The private deposits consist in a great degree of the reserves of the London banks, being the amounts which those banks require to have always at hand to work their own business. The rest consist of the deposits of merchants, traders, and others who have drawing accounts with the Bank. Of late, many old forms which stood in the way of persons desirous to open such accounts have been abolished; cheques are no longer limited to a minimum of 10*l*., but may be drawn of any amount; and every class of banking business is conducted for the private customer with ease and despatch, the Bank taking charge of Exchequer Bills and bills of exchange, of the collection of bills of exchange, receipt of dividends, &c.

Plate, title-deeds, &c., may be deposited by customers for safe custody. The Bank allows no interest on deposits of money, but, on the other hand, looks to the average balance of the customer's account as the source of repayment for the trouble and risk of keeping it, &c.; and in this respect is not more exacting than ordinary bankers, as no particular sum is required to be lodged on opening an account: the party must be known to be respectable, and in a position to require a banking account. The Bank has a printed code of regulations, under which drawing accounts are managed. No one is allowed to have a discount account who has not a drawing account.

Having premised these explanations, what we have to say respecting the two occasions of monetary crisis which have occurred since the Act of 1844 came into operation will be rendered somewhat more readily intelligible. It is the more important to the reader to be made acquainted with some of the leading particulars of these panics (as they are called), because each of them has occurred during the present law; each of them was met by the singular expedient of a government authorisation to the Bank to violate that law; and because it is not easy to meet with accounts of either of them, especially that of 1847; and, in fine, they are most advantageously studied when taken in connection, and the course which events took on each occasion brought closely into comparison and contrast.

All panics in this country have been preceded by the symptom of a gradually increasing withdrawal of bullion from the Bank. In the summer of 1846 a drain of this kind began to be perceivable; partly owing to the vast amounts required for the payment for the importations of corn and flour from abroad, and partly due to the construction of numerous railways then going on. Then the harvest of that year failed, and the potato crop failed, and the cotton crop failed; therefore it became necessary again to import corn largely: there was, besides, a still continuing demand for capital for railways, accompanied by a decline in the exports of manufactured goods. A heavy drain of gold therefore set in, and went on increasing up to January, 1847, the bullion in the Bank having, until that time, sufficed to meet the demands on it, without ever having been reduced so far as to create alarm. But in that month the drain steadily increased; the rate of interest in the general market was rising; the Bank raised its rate, which had been 3 per cent. since the middle of 1846, to $3\frac{1}{2}$, and then to 4 per cent.; it was not until April that they raised it to 5 per cent. The dividends were paid in July, and on July 30th the notes out with the public read 18,900,000*l*. On August 5th the Bank raised the rate of discount to $5\frac{1}{2}$ per cent., as their minimum rate for short bills; and then began failures of various great commercial houses, at first of those chiefly who were engaged in the corn trade, the price of corn having fallen 50 per cent. between May and September in that year. Several of the fallen houses, however, were stated to have been for some time in an unsound state. In September the pressure on the Bank for advances went on increasing, and early in that month the Bank had declared its readiness to make loans at 5 per cent., until the 14th of October, on the security of government stock. On that day the dividends are payable. On the last two days of September the advances were 149,000*l*. and 362,000*l*. respectively; but on the 2nd of October it was found necessary to declare that it was impossible to increase the amount of advances, and that the advances already made must be repaid before the day for the next payment of dividends. The whole commercial world was seized with alarm; confidence began to fail; and, as has been observed, "the consequences of sudden alarm cannot be measured; they baffle all ordinary calculation. Cash is then withdrawn, not because the circulation is excessive, but by the country banks and the town bankers, for the purpose of meeting possible demands upon them, and by the community at large, either directly from the Bank of England, or indirectly through the former channels, for the purpose of hoarding, from the dread of some imaginary or contingent danger. In such a crisis, every reduction in the amount of bank paper is so far from checking the drain that it aggravates the general distress." (Lord Overstone's Pamphlet, 1844.) It was stated to be quite impossible to repay the advances as required (they were, however, so repaid); there was, in fact, a general inability to meet commercial engagements, as it seemed; yet the Bank had gone farther in granting accommodation than they had done in the autumn of 1839, also a period of panic or collapse of confidence, arising, however, out of an unprecedented drain for the purchase of foreign corn, but unaccompanied by any severe pressure upon the commercial and mercantile interests. On the 1st of October, 1839, the notes and Bank post bills in the hands of the public were 16,800,000*l*.; on the 2nd of October, 1847, the whole amount of notes and Bank post bills in the hands of the public was 19,500,000*l*. On the former day the Bank held private securities to the amount of 13,290,000*l*.; on the latter day the amount was 21,260,000*l*. There was therefore, it may be said, an increase to the extent of 8,000,000*l*. in the accommodation afforded by the Bank in 1847 as compared with 1839. How was this accommodation afforded? The Bank is the bank of the government, with which the government constantly has a drawing account, and sums paid on account of Customs, Excise, and other taxes are immediately lodged in the Bank. Accordingly, towards the end of each quarter, when the dividends on the government stock are payable, the government balances in the hands of the Bank greatly accumulate, and the Bank takes advantage of this circumstance to extend accommodation to the public, by lending out sums on securities, to be repaid before the time when the dividends become due, and when the money will be wanted to discharge them. When the Bank makes loans of this kind, for a period determined by its own convenience, and not by the desire of the borrower, the practice is to make them at a lower rate of interest than the then rate of discount. On the whole, then, there was no want of accommodation on the part of the Bank, where no bill was ever, during the whole of the pressure, refused discount, which would have been discounted in an ordinary season and under usual circumstances, though the whole demand for discount was thrown upon the Bank; the difficulty arose from the wholly anomalous and abnormal circumstances arising from an expenditure in the purchase of foreign corn of no less than 33,563,476*l*. within the previous fifteen months, of which 14,240,000*l*. had been paid between July and October; whilst during the same fifteen months 80 millions or 90 millions had been abstracted from other pursuits to be expended on railways. Moreover, the country bankers had required large quantities of bank notes, in order to be provided, not so much against the demands of their note holders, as of their depositors. The Scotch banks especially, with their enormous deposits, were obliged to make heavy drains of gold; and it was in evidence that all this was much aggravated by the hoarding of gold and notes to a very large extent in the hands of individuals.

On the 25th of October, the government thought fit to interpose, and a letter was addressed to the Governor and Company of the Bank by the First Lord of the Treasury and the Chancellor of the Exchequer, recommending and advising the directors, if it should become necessary for the accommodation of the public, to advance their notes upon approved security; and that if thereby the Act of 1844 should be infringed, the government would apply to Parliament and ask for an indemnity for those who had violated the law, and for the ministers who had advised it. The government also mentioned the rate of interest, viz., 8 per cent., at which these advances ought to be made. As soon as the letter became known the panic at once ceased.

The rate of interest at this time, it is to be observed, was in general higher than that (especially considering the commission) charged by bill-brokers, and which must be added to their nominal rates of discount; interest was at from 6 to 7 per cent. in Hamburg, and not much lower throughout Germany: the rate of 7 per cent., obtained at New York, and in the United States generally the rate was upwards of 7 per cent. The object of the government interference was not the vain hope of *creating* capital, still less to buoy up a fictitious credit, but it was to restore credit, to resuscitate confidence, to set loose the circulation of the country, which, as it were, was frozen by alarm. Persons who had means of their own, and securities to offer, immediately found available the assistance placed at their disposal in consequence of this measure, so as to be able to carry on their business without further difficulty. In fact, every body seeing that the convertibility of the bill of exchange was no longer at hazard, or matter of difficulty, and that for sound commercial paper there were ample means of discount, confidence returned; trade gradually fell back into its usual channels: the interference of the government, in fact, prevented a general and contemporaneous failure from inability to meet immediate demands, not from insolvency.

At the time at which the letter was issued, there were eight millions of bullion in the bank; the foreign exchanges had turned so as to be decidedly in favour of this country, so that an influx of bullion was well assured. Now for nine months the drain had been going on; and it was only to the operation of the Act of 1844 that the country was indebted for the possession of that mass of wealth after such a long process of exhaustion; not above a quarter of a million of bullion was purchased by the Bank during the summer; in fact, it was to the operation of that Act during the early part of the year, that the country was saved from the necessity of a suspension of cash payments, one of the most distressing calamities that can befal it; for, though on the 25th of October, the bullion in the issue department was 7,865,000*l.*, yet the reserve was 1,994,516*l.*: and though the Court of Directors by a formal resolution conveyed to the government their conviction, that as far as the Bank was concerned they could comply with the provisions of the law and maintain their position, yet at the same time they confessed that if an application for assistance came to them from the great provincial banks, or from other quarters, they could not grant the accommodation, and that they might possibly be obliged to curtail the accommodation they had already given.

The next occasion of monetary crisis which befel this country was in 1857. As we have observed, all panics in this country are found to be preceded by a withdrawal of bullion from the coffers of the Bank.

The following table will show the relative amounts of bullion and reserve in the Bank, and the rate of discount during the latter half of the year 1857, the panic or pressure having occurred in November of that year.

1857.	Bullion.	Reserve.	Rate of Discount at the Bank.
	£	£	
June 5 . . .	9,451,000	5,782,000	6½ per cent.
June 18 . . .	10,409,000	6,981,000	6 ,,
July 16 . . .	11,242,000	6,408,000	5½ ,,
October 8 . . .	9,751,000	4,931,000	6 ,,
October 12 . .	8,991,000	4,115,000	7 ,,
November 9 . .	7,719,000	2,834,000	10 ,,
November 10 . .	7,411,000	2,420,000	10 ,,
November 11 . .	6,666,000	1,432,000	10 ,,
November 12 . .	6,524,000	581,000	10 ,,

Now one indication of the difference in the state of the cases of 1847 and 1857 is the following. It will be found on closely comparing the two periods that the 25th Sept., 1847, held an analogous position as regards the progress of the panic of that year with 19th Oct., 1857, as regards that of the latter year. But the state of the bullion and reserve was as follows in the two years:—

	Bullion.	Reserve.	Rate of Discount.
	£	£	
September 25, 1847 .	8,782,000	4,112,000	5½ per cent.
October 19, 1857 .	8,991,000	4,115,000	8 ,,

So that with the same bullion and the same reserve, virtually the rate of interest had sustained an increase of no less than 2½ per cent., but it is necessary to bear in mind that the country had been accustomed for the whole period of the Russian war to rates of 6 and 7 per cent., which were higher than ever had been known previously; therefore there is not so much room for astonishment as if the rise had been at once from 5½. Before going further into the comparison between the two periods it will be necessary to trace the rise of the panic of 1857, and point out what was the conduct of the Bank and the Government in regard to it. In the month of August of that year the Bank had not had any reason to apprehend any necessity for taking measures to prevent the efflux of bullion. The prospects of harvest were very good; there was no apprehension that commerce at that time was other than sound. The merchants, it was true, were importing, notwithstanding the enhanced prices caused by the war, but they had done the same successfully in the same circumstances in the previous years. Things were in this state up to Sept. 15, when news arrived from America of the great depreciation of railway securities to the extent of 10 or 20 per cent., it being supposed that American securities to the value of 80 millions sterling were held in this country. The Ohio Life and Trust Company, which acted as bankers to a very large extent, had also failed. The real value of the exports from this country to America, in 1856, was 21,476,000*l.*, of which much was unpaid at this time. In the beginning of October, further accounts from America stated the artisans to be falling out of employment; discounts had risen from 18 to 24 per cent. On the 7th, news came of the suspension of the banks in Philadelphia and Baltimore. On the 8th, the bullion was fast leaving the Bank of England; its discounts and advances were as high as 11,648,000*l.* The rate of discount was raised to 6 per cent., the rate at Hamburg being 7½; and on the 12th, the Bank rate was raised to 7 per cent., which was further raised on the 19th to 8 per cent.; but in the meantime, further bad news came from America, where many additional failures had taken place. The Bank of France had lost in one week upwards of one million sterling. On the 20th Oct. an application was made to the Bank of England for assistance from the Borough Bank of Liverpool, but upon terms that were inadmissible, and were rejected. On the 26th, a deputation came up from the Western Bank of Scotland, but their deposits being 6,500,000*l.*, their issue of notes 480,000*l.*, bills discounted 3,600,000*l.*, of which it was estimated 970,000*l.* would not be paid at maturity, and loans on open account having been made to 2,560,000*l.*, and also a large quantity of liabilities falling due in London, the Bank of England declined to undertake the responsibility of helping them through their difficulties. They were supposed to have lost very largely from the failure of American houses with whom they were involved. There was at this time a run on the banks in Ireland, and on the 5th Nov. the rate of discount was raised to 9 per cent.; there having been on the 30th Oct., a demand for assistance from other banks in Scotland, and 50,000 sovereigns had been sent down to one bank there, and 80,000 to Ireland. Between the 5th and the 10th Nov., took place the failure of Dennistoun's house, whose acceptances were supposed to reach nearly 2,000,000*l.* Also on the 9th, the Western Bank of Scotland stopped, the failures in London were on the increase, and the discount was raised to 10 per cent. On the 10th a leading discount-broker's house applied to the Bank for accommodation, to the extent of 400,000*l.* The City of Glasgow Bank suspended. The discounts and advances at the Bank of England for that day were 1,116,000*l.*, and on that day and the next there was sent down to Scotland gold to the value of one million sterling, to enable the banks there to strengthen their tills.* The run on the banks in Ireland was on the increase. On the 11th, Sanderson & Co., large bill brokers (who had stopped payment in 1847, but had afterwards paid every one, and recommenced business), failed, their deposits being supposed to be four millions, and their liabilities on bills of exchange five millions.

On the 12th, about three o'clock, the Bank received a letter signed by the First Lord of the Treasury and the Chancellor of the Exchequer, informing the directors that if they should be unable in the emergency to meet the demands for discounts and advances upon approved securities without exceeding the limits of their circulation prescribed by the act of 1844, the government would propose to Parliament a bill of indemnity for any excess so issued, and expressing an opinion that the rate of discount should not be reduced below the existing rate (10 per cent.). At that time the bullion was 6,524,000*l.*, and the reserve 581,000*l.*; the Bank having sold 3,000,000*l.* of government securities, besides exchequer bills. But there had been for some time a continued pressure on the Bank for accommodation. On the 24th of October, the loans and advances were 10,100,000*l.*; on the 5th of November, they had risen to 12,808,000*l.*; on the 11th, they were 15,900,000*l.*; and after the issue of the letter they went on increasing until they attained the maximum, on the 21st of November, when they were 21,600,000*l.*: exceeding the amount of the deposits, which were 20,823,000*l.* But for the aid of the Treasury letter, the Bank would not have ventured to carry the accommodation given to the mercantile community so high. What then was the practical operation of the letter? It was this: it enabled the Bank to transfer from the issue department to the banking department such a quantity of notes as might be sufficient to meet the emergency, whatever that quantity might be. The Bank took actually from the one department to the other 2,000,000*l.* in notes, and thus they had so much additional means of discounting and advancing upon securities. In point of fact, not quite 1,000,000*l.* of this sum was needed, or used; because, as soon as the commercial world became aware that the letter was issued, and that the supply was unlimited from whence to obtain accommodation to those who had good securities to offer, or good bills to be discounted, confidence began to revive; the fears for the convertibility of good paper subsided, and the panic might be said to have passed away. This was the mode in which the issue of the letter operated; in other words, this was the advantage gained by violating the Act of Parliament.

What was the advantage of having adhered to it up to that time? The answer is, that if the bullion had been much lower than it was on the 12th, and had borne any appearance of going lower still, the Bank would not have ventured, even with the letter in their hands, to go on making the subsequent advances which they did, for in such case they would have felt that it became necessary to provide for the convertibility

* The pressure from the Scotch Banks was also an element in the panic of 1847. See 3 'Hansard's Debates,' vol. 95, col. 398.

of the note; and it was the provisions of the Act which prevented the Bank from issuing more notes than in the proportions to the bullion which the law requires, and so gold would have gone out faster by the action of the foreign exchanges, and the directors would have been left with less gold as the panic increased. The Act therefore secured for the public the power in the Bank to give more aid at the time when the pressure was the severest than it otherwise would have possessed, and thus rendered the directors more careful in securing and retaining the bullion than they were before 1844, and enabled them to resist the influence and pressure which the mercantile community would otherwise possibly exert upon them with success, and which would end to lead them into less judicious courses, or at least leave them less free to act on their own discretion than now they are able within the statutory limits to act. The authorities of the Bank appear to consider the statute to operate, not as a clog, but as a support,—not as a hindrance, but as an aid. It is material however to observe the state of the foreign exchanges during this period; because, through the whole of it, they were not, according to the best authorities, such as apparently to pay for sending gold abroad. Thus, on the 10th of November, the exchanges were: Hamburg, three months, from 13·12 to 14; Amsterdam, short, from 11·16 to 19; Paris, short, 25·35 to 45; and therefore the Bank was freed from any apprehension that the advances they made in consequence of the Treasury letter could have any adverse effect on the foreign exchanges with this country. The American exchanges however were very unfavourable to this country during all this time, and the exchange would have given a large profit on the transmission of gold; but on the above day, the failure of the American banks being known here, there was very little probability of gold flowing from this country to America: indeed, the distrust between the two countries was such, that gold both came and went. Both the Bank and the commercial world, there is little doubt, governed their conduct in the middle period of the pressure,—that is, after it was undeniable that there was an actual stagnation of credit and confidence,—by the conviction that a letter would be issued, as had been done in 1847, and that accounts for the contrast between the two panics: in 1847 there was more of alarm, and of unreasonable alarm or panic; in 1857 there was greater commercial distress, but less panic. In the former year, however, the letter was issued at such a period of the pressure that it never became necessary to act upon it so as to exceed the limit of issue laid down by the statute. In 1857, but for the expectation of the letter issuing, the Bank must have refused to discount considerably before the 12th, and would have protected themselves by retaining the notes as they came in from the payments of the bills already discounted, or, as it is called, the run off of the discounts. Some of the indications of alarm respecting the state of monetary and business affairs in London during this period may be mentioned. Well-established solvent houses were found bringing their bills to be discounted by the Bank, who were known not to be actually pressed for money; but the apprehension of being left without the means of meeting future possible pressure made them lose no time in realising their securities. The London bankers' deposits—the Bank of England being the bankers' bank, where they keep the larger portion of their cash reserves—very much increased all through the alarm period. The same was found to be the case of the merchants' and traders' deposits. This is a decided symptom of alarm, at least since the Act of 1844. In the last quarters of the years 1838 and 1839, which were periods of prosperity and of pressure and distress respectively, the deposits of the London banks with the Bank of England were 812,000*l.* and 615,000*l.* respectively, showing the deposits to have sunk materially during the period of crisis. In periods of apprehension and collapse of credit, everyone is urged to contract his operations, and endeavours to draw in his resources, in order to be prepared as much as possible for any demands that may come upon him; and the bankers are content in such a season to forego the usual profits that they make on their deposits rather than be without the means of answering any amount of demand that it is at all probable will be made upon them. Accordingly, instead of discounting bills, as usual, with their deposits, the bankers very generally discontinued giving discounts between the 9th and 12th of November, and the whole of the discounting of London nearly centered in the Bank of England,—another proof of apprehension. The bankers' deposits with the Bank at the close on the 12th read 5,458,000*l.*, and subsequently, and before the end of the year, the amount rose beyond that sum: and between the 7th and the 19th of Nov. the balances of merchants, traders, and private persons in the Bank books were increased by one million. Another symptom of alarm is found in this, that consols continued to rise during the most critical moments of the period, which is attributed to timid persons withdrawing their deposits from banks in order to have the better security of the government.

If the letter had not issued, what would have been the consequence? The Bank must have refused to discount any more bills; this would have materially augmented the alarm of the London mercantile community. It is probable that the demands of the depositors and creditors of the banks in London would have increased upon them so much as to have compelled them to withdraw portions at least of their deposits from the Bank of England. Now, as the Bank had been employing largely these bankers' deposits in giving accommodation by the discounting of bills, unless the notes had come back to the Bank by the running off of the discounts more rapidly than the bankers' claims for their money increased upon the Bank, it must have stopped payment in the banking department. Then, persons having acceptances to meet payable at their bankers, on the supply of notes being stopped at the Bank of England, would have been unable to have met those acceptances, and widely-spread failures would have ensued. It seems clear that this must have been the result, inasmuch as the Bank had only at that time (without the letter) power to pay away about 2,000,000*l.*; that was the whole that it had the power to pay away, whether at the Bank or at its branches all over England. It was assuredly not in a condition to answer the claims that not very improbably might have been made upon it by bankers and other persons, and it must therefore have suspended payments in the banking department. But even this would not have affected practically the question of the convertibility of the Bank note, because by the operation of the Act of 1844, to insure that, the Bank had nearly 7,000,000*l.* in the issue department. It must be borne in mind, however, that the Bank would not have acted as it did in giving assistance to the mercantile community, but for the impression that at the worst what had taken place in 1847 might occur again; it would still, it appears, have considered it to be its duty to make common cause with commerce, but it might both have raised its rate of discount earlier and have diminished the *echéance* of the bills discounted, and possibly might have succeeded without the aid of the letter, but for the unexpected demand from the banks in Scotland to an immense amount for sovereigns, which demand had the effect of a foreign demand in this respect, that the sovereigns could not be expected to return to this country, and therefore were so much abstracted from the English circulation.

In another view the effect of the letter was to place the Bank in excess of its statutory issues by 2,000,000*l.* for the whole period, from 13th Nov. to 24th Dec., both days inclusive; on which day the 2,000,000*l.* was returned to the issue department, and the Bank found itself in a position to lower the rate of discount below 10 per cent. The whole sum advanced to the public by the Bank between the 12th Nov. and the 1st Dec., 1857, was 12,645,000*l.* The course of the rates of discount for 1858 was the following:—

The Bank rate which in November 1857 was 10 per cent., as has been said, had been reduced between that date and the end of December to 8 per cent., was in January, 1858, varied to 6, and eventually to 4 per cent., until on the 11th of February, it was 3 per cent. Then the Bank of France having reduced its terms of accommodation to 4 per cent., the influence of the change was felt in the continental cities, and the average terms for accommodation at Hamburg had in the interval fallen to 1½ and 2 per cent.; at Amsterdam to 3½ per cent. In the course of September and October the Bank of France had adopted the rate of 3 per cent. Early in December the Bank of England reduced its terms of discount to 2½ per cent.

As in 1847, a vast number of fictitious bills were discovered by the panic of 1857 to be in existence: the number was supposed, however, to be much greater in the latter year, and by many persons this was said to be an effect of the new mode of banking under which the Joint Stock banks took money on deposit accounts from persons who put small sums into their hands for the sake of the interest which these banks pay upon such accounts, in fact, using those banks, not for the ordinary purposes of banking, but as a medium of investment; the effect of which was said to be, to cause the bankers and their brokers to be less cautious as to the character of the bills they discounted, inasmuch as the deposits being placed with them at call, and also bearing interest, it became essential for the bankers to employ the money immediately, and therefore, without having the same opportunity for circumspection and inquiry, as is had in ordinary banking transactions. On this we shall have some remarks to offer under the head of *Joint Stock Banks*. But it was the complaint in 1847, as it also was in 1857, that persons having good mercantile bills to offer, respectable persons, could not obtain the means of converting them into money. There was no question in that year, any more than in 1857, as to the convertibility of the Bank note. It is believed to be the meaning of Parliament in the Act of 1844 to make the bullion in the issue department, and also the securities there placed, responsible to the holders of notes, and available in support of the notes with the public, exclusively of the claims of the depositors in respect of their deposits, as such, in the banking department.

One principal effect of the Act of 1844 is this: it enables every person to convert into Bank notes any amount whatever of bullion that he may choose to carry to the Bank, and authorises the issue of notes besides to the extent of 14 millions sterling upon security; or any one taking his bullion to the Bank may receive back the value in gold coin at the rate of 3*l.* 17*s.* 9*d.* an ounce, a charge of 1½*d.* an ounce being in addition made by the Bank as remuneration for the loss of time and the trouble of getting the gold turned into coin. The reason why the sum of 14 millions was fixed upon by the framers of the Act, was the following: Previous to 1844 the circulation of Bank of England notes seldom reached 20 millions or fell so low as 16; and therefore Sir R. Peel assumed that the circulation which was necessary for the country, and which could not be materially reduced in any ordinary state of society, was about 14 millions. This amount the Bank was allowed to issue upon securities; and it was also provided that, in case of the note-issuing banks ceasing to issue, the Bank might, by order in council, be authorised to issue on securities to two-thirds of the value of the circulation previously authorised to be issued by such country banks. This provision has raised the total secured issue of the Bank from 14,000,000*l.* to 14,475,000*l.* Under the system established by the Act of 1844, for every note which the issue department may at any time issue over and above the last-mentioned sum (issued on security), an equal amount of coin or bullion must be paid into its coffers. Probably, however, in framing the measure, the operation of deposits and the question of the reserve were not sufficiently considered either by those who were for or against the alteration. The pressure of 1847 was, it has been said, caused by the conduct of the directors in making immoderate engagements and neglecting to provide an adequate reserve for their own protection. "I do not deny" (said Sir R. Peel in 1847, Hansard's Debates, 95, col. 656) "that one of the objects contemplated by the measure of 1844 was the prevention of the convulsions that had heretofore occurred in consequence of the neglect of the Bank of England to take early precautions against the withdrawal of its treasure." But he owned, at the same time, that there was no imperative obligation on the directors to take these precautions, and he admitted that the Act had failed in effecting this first object. The other two objects, of maintaining and guaranteeing the convertibility into gold of the paper currency, and the prevention of the difficulties which arise at all times from undue speculation, being aggravated by the abuse of paper credit in the form of promissory notes, according to the provisions of the Act for limiting the issue of notes by the private bankers, which we shall treat of in full under the head of *Private Bankers*,—both these objects, he affirmed, had been secured. But it is certain that the Bank is placed in a very peculiar position by the operation of the Act. We cannot, perhaps, as the Act has been administered on two occasions, which strongly tested its efficacy, any longer be in danger of such a peril as was imminent in 1825, when, as Mr. Huskisson said, the country was within twenty-four hours of a state of barter; and when, as Lord John Russell assures us, "it is certain that the Bank had prepared a notice that its payments were to be suspended for a time" (Hansard's Debates, 95, col. 631); but still the responsibilities of the Bank are materially increased. It is utterly impossible that an establishment possessed of so large a capital should not exercise a most powerful influence, either for good or for evil, on the commercial interests of the country, and it is therefore a matter of vital importance that the management of the Bank of England should be conducted soundly and wisely. "If by our legislation we had provided that the Bank should at all times consider the interests of the public and not of their proprietors; if, on the other hand, the public were generally agreed that the Bank should look to its own interests only, and that on occasions of distress no man need go to the Bank for any other accommodation than he would have as a customer in ordinary times: in either of these cases their duty would be simple and the problem easy to solve. But acting at one time as proprietors, employing the money in their hands to objects of mercantile profit, and then being suddenly called upon to consider the great interest of the state, their position is difficult and perplexing beyond what can be easily explained." (Id. cols. 635, 636.)

Having now brought down to the present time our account of the principal events in the history of the Bank, with the view of dwelling chiefly on those points which seemed the best qualified to afford useful information to the reader, we proceed to state what is the internal constitution of the Bank.

By the original charter, the management and government of the corporation is committed to a governor, deputy governor, and twenty-four directors. The directors are elected, on the 1st of May in each year, by the proprietors of Bank stock, who vote in proportion to the quantity of Bank stock which they hold, provided that no proprietor shall have a vote who holds less than 500*l.* Bank stock, and no proprietor shall give more than four votes. The governor is to hold 4000*l.* of stock, the deputy governor 3000*l.*, and each director 2000*l.*, during office. In practice, no director holds more than the above amount; and the governor and deputy governor, when their year of office is ended, immediately reduce their several amounts of stock to the sum which qualifies a director. The directors are elected from such of the proprietors as are merchants of the city; a banker is seldom or never admitted to a seat in the direction. It is believed that no director has ever been allowed to derive advantage, by special accommodation or otherwise, in his private concerns, from his position as director. In the panic of 1857, not a shilling was advanced to any one of the directors. The directors, it is to be observed, though by law elected by the proprietors, are not appointed in virtue of anything in the nature of a popular election or nomination of the proprietors. In practice, a selection is made by what is called "The House List," which contains the names of the persons whom the existing Board of Directors deem proper to be appointed, and this list is always adopted by the proprietors at the annual meeting on the 1st of May; eight directors going out of office each year. But this arrangement has not been found to be quite convenient for the general interests of the institution, and a majority of the Board of Directors lately came to a resolution which was communicated to the government of the day, suggesting that one-sixth instead of one-third should go out annually. Thirteen directors (of whom the governor or deputy governor are always to be one) are a quorum, to constitute a Board of Directors. Four general courts are to be held in every year, in the months of April, July, September, and December; and special general courts may be summoned at all times, upon the requisition of nine qualified proprietors.

The total number of proprietors is between 5000 and 6000. There are half-yearly meetings of the proprietors held for the declaration of dividends on the capital stock of the company, which are fixed by the directors.

The chief cashier is the banker; under whose superintendence takes place the business of receiving and paying money: he or his deputy are bound to reside on the Bank premises.

The accountant-general of the Bank superintends the accounts of the public creditors, and all the business connected with the management of the National Debt.

The *dividends* on Bank stock from the establishment of the company down to the present time have been as follows:—

1694 . . .	8 per cent.	1767 . . .	5½ per cent.
1697 . . .	9 "	1781 . . .	6 "
1708 to 1729	varied from 9 to 5½ per cent.	1788 . . .	7 "
1730 . . .	6 "	1807 . . .	10 "
1730 . . .	5½ "	1823 . . .	8 "
1731 . . .	6 "	1839 . . .	7 "
1738 . . .	5½ "	1852 . . .	7½ "
1747 . . .	5 "	1853 . . .	8 "
1753 . . .	4½ "	1856 . . .	9½ "
1764 . . .	5 "	1857 . . .	10 "
		1858 . . .	11 "

The Bank is bound to give gold for its notes, both in Threadneedle-street and at its branches, to any one who requires it; but it besides takes upon itself the function of facilitating the supply of the silver coinage to the public, that supply being chiefly derived from the Bank of England through the provincial and London bankers. The Bank also performs the same duty when required with respect to the copper coinage.

The Bank acts as the agent of the government in the management of the National Debt. It receives and registers transfers of Stock from one creditor of the public to another, and makes the quarterly payments of dividends on the debt.

The balances of money belonging to the state are kept by the Bank, which receives all payments on account of the revenue made by the receivers-general to the credit of the government, and makes payments for the government in the same way that a private banker acts for a customer.

The Bank of England never re-issues any of its notes. The cost of the note circulation is about 160,000*l*; though the expense is much augmented by the above practice, what is lost in economy is considered to be more than compensated by the advantages. The Bank is enabled by this practice to make all its issues of notes to bankers and other large customers in consecutive numbers; which gives great facility and saves the Bank much time in recording the notes issued, which is always done; it also saves the bankers much time in enabling them to record the numbers of the notes which they issue to their customers, and facilitates the detection of forgeries. The notes, when returned, are immediately cancelled, and in this way about 29,000 or 30,000 notes are destroyed daily.

IV. *The Art of Banking, as carried on by private establishments and joint-stock associations in London, in other parts of England, and in Ireland.*—The Italian merchants who, under the name of Lombards, settled in England during the 13th century, and previously to that time the Jews, performed the greatest part of the money business of the country. They were not, however, bankers, in the modern acceptation of the word, and in fact the business of banking does not appear to have been carried on among us earlier than the middle of the 17th century. The goldsmiths of London, who before that time had restricted their trade in money to the purchase and sale of foreign coin, then extended their business by borrowing and lending money. The latter part of their business—that of lending—was principally transacted with the king, to whom they made advances on the security of the taxes. They allowed interest to the individuals from whom they borrowed, and the receipts which they gave for deposits passed from hand to hand in the same manner as Bank notes have since circulated.

The taking of interest for the use of money was not rendered legal in England until 1546, when the rate that could be demanded was fixed at 10 per cent. In 1624 the legal rate was reduced to 8 per cent., and a further reduction to 6 per cent. took place in 1651. At this rate it still remains in Ireland, but was lowered in England to 5 per cent. in 1714, at which it now continues. These limitations have always been productive of evil. Money-lenders by profession will always be ready to take advantage of the necessities of borrowers, and being left without competitors among the more conscientious capitalists, demand not only a monopoly price for the use of their money, but also a further sum proportioned to the risk and penalties attending discovery. The Lombard merchants were accustomed to demand 20 per cent. interest, and even more, according to the urgency of the borrower's wants.

The merchants of London had been used to deposit their money for security at the Mint in the Tower of London, whence they drew it out as occasion demanded; but in the year 1640 King Charles I. took possession of 200,000*l.* thus lodged, which of course put a stop to that practice. This state of things preceded and most probably led to the extension of the business of the goldsmiths, as just explained.

This business soon became very considerable, and was found convenient to the government. In 1672 King Charles II., who then owed 1,328,526*l.* to the bankers, borrowed at 8 per cent., shut up the Exchequer, and for a time refused to pay either principal or interest, thus causing great distress among all classes of people. Yielding to the clamour raised against this dishonesty, the king at length consented to pay 6 per cent. interest, but the principal sum was not discharged until forty years afterwards.

Private Banking.—There are three private banking-houses still carrying on business in London which were established before the Bank of England. The London bankers continued for some time after that event to issue notes, but have long since ceased to do so, acting solely as depositaries of money, discounters of bills, and agents for bankers established in the country. No restriction has ever existed which prevents private banks in London, having not more than six partners, from issuing their notes payable to bearer; that they have ceased to do so has arisen from the conviction that paper money, issued on the security of only a small number of individuals, could not circulate profitably in competition with that of a powerful joint-stock association. Private bankers in London do not make any charge of commission to their customers, and generally grant considerable facilities to them, both by discounting bills and by temporary loans, either with or without security. Even where this kind of accommodation is not required, it is almost a matter of necessity for every merchant or trader carrying on considerable business to have an account with a banker, through whom he makes his payments, and who will take from him the daily trouble of presenting bills and cheques for payment.

The profits of London bankers are principally derived from discounting mercantile bills either for their customers, or, through the intervention of bill brokers, for other parties. They have great facilities as regards the security of this business, from the unreserved confidence which they are accustomed to place in one another as to the credit of their respective customers.

The great amount of money transactions daily carried on in London has led to the invention of a simple and ingenious method for economising the use of money. Almost all these payments are in the form of cheques upon bankers, or of bills of exchange addressed to bankers for payment, or accepted payable at their banking-houses. At three o'clock every afternoon a clerk from each banking-house being a member of the clearing-house, proceeds to a house in Lombard Street, called the clearing-house, taking with him all the drafts on other bankers which have been paid into his house that day, and deposits them in drawers allotted to the different bankers. Another clerk is afterwards sent who delivers to the first all the drafts paid into the banking-house up to four o'clock, and these are distributed in the manner already described. He then gives credit to each respectively for the amount of drafts on his own bank which he finds in his own drawer. Balances are then struck, and the claims thus found are transferred from one account to another, and so wound up and cancelled, that each clerk has to settle with probably only two or three others, and transactions to the extent of millions are settled ultimately by means of cheques upon the Bank of England, without the intervention of any notes or coin whatever. Each banking-house that is a member of the clearing-house has an account with the Bank of England, and so the claims of any one of these banks upon another are satisfied by transfers in their respective accounts at the Bank of England. Other London bankers who are not members of the clearing-house have similar accounts with the Bank of England, and pay the claims of the City bankers by cheques on the Bank of England. The oldest banks in Fleet Street, the Strand, at Charing Cross, and generally the banks in Westminster, are not members of the clearing-house, but pay the demands of the City bankers by notes handed over the counter. It is to be observed that the use of cheques, which has of late increased so much, the clearing-house system, and all the various forms of transfers of credits by which country bankers settle their balances in London with each other, and by which London bankers settle their balances with each other, are various modes of economising the use of Bank notes and of time; and the prevalence of this course of business accounts for the fact of the Bank of England notes with the public remaining generally so near the same amount; for these banking expedients have met the increased requirements of the increased trade of the country for more circulating medium, which they supply the place of, confidence being the base of the improved system. In seasons of panic, however, it may possibly appear that in proportion as in ordinary times monetary transactions are habitually thus conducted, superseding the use of coin or Bank of England notes, so in a condition of collapse of credit and confidence when every creditor is anxious to be paid in coin or notes, the difficulties of the period will be multiplied.

The country bankers have lately taken up the idea of having a clearing-house in London for the purpose of obviating many inconveniences which country bankers incur in realising cheques drawn upon other country bankers, whose banking-houses are not in the same town. The course of business in such cases has been, for the banker receiving the cheque to transmit it by post to the banker on whom it is drawn, with a request that the amount may be ordered to be paid in London, to the credit of the remitting bank with their London correspondents or agents. An arrangement has lately been brought nearly to completion by which this business will in future be effected through the present clearing-house in Lombard Street. The bills or cheques which bankers do not choose to cash are returned, after the clearing, to the houses by whom they were presented, and by whom the amount is then refunded. Drafts which are not paid in until after four o'clock are sent to the banking-houses upon which they are drawn to be marked for payment on the following day; and this proceeding, which has been adopted for the convenience of the bankers in making up their accounts daily at a certain hour, is of the same effect as regards the drawers and the persons by whom the drafts are paid in, as if the payment had actually been made.

There were very few country bankers established previous to the American war, but after the conclusion of that contest their numbers increased greatly. In 1793 they were subjected to heavy losses, consequent upon the breaking out of the war, and twenty-two of them became bankrupt. The passing of the Bank Restriction Act was the signal for the formation of many establishments for banking in the country. In 1809, the first year when bankers were required to take out a licence, the number issued was 702, which gradually rose to 940 in 1814. In that and the two following years 89 of these bankers failed, and their numbers fell off greatly. In each of the years 1825 and 1826 there were about 800 annual licences issued, but their numbers were again reduced by eighty bankruptcies, and in 1832 only 636 licences were demanded.

Country banks in England are all of them banks of deposit and of discount; they act as agents for the remittance of money to and from London, and for effecting payments between different parts of the kingdom. Some of them are also banks of issue, and their notes are in many cases made payable at some banking-house in London, as well as at the place where they are issued.

The Bank Charter Act of 1844 (7 & 8 Vict. c. 32), besides the provisions regulating the Bank of England, the effect of which has been already stated, contained various enactments in regard to private banks by which they are at present regulated. As regards the issue of notes, with the intention of finally extinguishing all issues of paper currency except the notes of the Bank of England, no banker, it was enacted, except he were issuing on the 6th of May 1844, was in future to issue notes in any part of the United Kingdom; it was not to be lawful for any banker to draw, accept, make, or issue in England or Wales any bill of exchange, or promissory note, or engagement for the payment of money payable to bearer on demand, or *to borrow, owe, or take up* in England or Wales any sum on the bills or notes of such banker payable to bearer on demand; but any banker on the above date issuing under the authority of a licence in England or Wales his own bank notes, was to continue to issue (under conditions to be mentioned presently). Also, the right of any company or partnership to continue to issue was not to be prejudiced or affected by the personal composition of the company or partnership, either by the transfer of shares or by the admission of any new member or partner, or by retirement of any present member or partner, provided that no company or partnership consisting, on the 19th of July 1844, of only six or fewer persons, was to issue at any time after the number of partners should exceed six. Any banker who should, after that date, being entitled to issue, become bankrupt, or cease to carry on the business of a banker, or discontinue to issue, was disabled to issue in future. Then the extent to which each bank was to be entitled to issue was limited in this way: the average amount of notes which the bank had in circulation during a period of twelve weeks preceding April 27, 1844, was to be ascertained from the returns made by the bank under a previous statute (4 & 5 Vict. c. 50), and this amount it was bound not to exceed,—that is to say, the average of the circulation for a period of four weeks was not to exceed that amount. In case however of two or three banks, each consisting of not more than six persons, uniting, the aggregate of the issues which they were previously authorised to have is to be the limit, which the average of their four weeks' circulation is not to exceed; but no such united bank is to retain the privilege of issuing after the number of its partners exceeds six. The penalty upon exceeding the limit so appointed for the monthly average is fixed at the value of the notes in excess; and every issuing banker is to transmit weekly to the Stamp Office an account of his notes in circulation on every day during the week ending on the next preceding Saturday to the day on which he transmits the account; and, also, he is to send therewith an account of the average amount of his notes in circulation during the same week, and on completing the first period of four weeks, and so on, completing each successive period of four weeks, he is to annex to such account the average amount of his notes in circulation during the four weeks, and also the amount of notes he is authorised to issue; and refusal or neglect to make the return, or making a false return, is punishable by a penalty of 100*l.* The average is obtained by dividing the aggregate amount of notes in each period of four weeks (which is always to end on a Saturday) by the number of days of business in the four weeks. There were some other minor provisions for the purpose of inducing issuing bankers to surrender the privilege of issuing on certain terms of compensation, which it is not material to state at length. On the other hand, it was permitted to any society, or company, or partnership, though exceeding six in number, carrying on the business of banking in London, or within 65 miles, to draw, accept, or endorse bills of exchange not being payable to bearer on demand, repealing all former Acts to the contrary.

A moderate rate of interest is allowed by some country bankers upon deposits which remain with them for any period beyond six months; some make this allowance for shorter periods. Where a depositor has also a drawing account, the balance is struck every six months, and the interest due upon the average is placed to his credit. Upon drawing accounts, a commission, usually of a quarter per cent., is charged on all payments. The country banker, on his part, pays his London agent for the trouble which he occasions, either by keeping a certain sum of money in his hands without interest, or by allowing a commission on the payments made for his account, or by a fixed annual payment in lieu of the same.

The portion of funds in their hands arising from deposits and issues which is not required for discounting bills and making advances in the country, is invested in government or mercantile securities in London, which, in the event of a contraction of deposits, or demands by the note-holders for gold, can be made immediately available.

The establishment of banks throughout the kingdom has contributed materially to the growth of trade. Without them it would hardly be possible for a manufacturer employing any great number of hands to collect the money required to pay the weekly wages of his people. It is not a valid argument against their utility that occasionally, by the facilities they have afforded, the tendency to overtrading has been encouraged; but it is to be hoped that the light which has of late been thrown upon the nature of this branch of business will be the means of checking the evils, without much diminishing the good, which it is calculated to effect.

The framers of the act of 1844 undoubtedly contemplated a period when the only source of the paper circulating medium should be the Bank of England; and the Bank seems accordingly to act towards the provincial banks of issue as though they were intruders upon its special province, and does not think fit in general to afford bankers of that class the accommodation in some respects which it extends to others. "It is very well known that the Bank of England will never discount a bill of any quality whatever for a note-issuing banker." (Evidence before Committee on Banks, &c., 1858, Q. 2785.) The Bank, it seems, has laid down rules which preclude it from discounting even Rothschild's acceptance brought for discount by a banker of this class. In consequence of this, these bankers are compelled to hold in their tills, in seasons of pressure, a much larger amount of bank notes than they would otherwise be under the necessity of keeping, if they had the usual facilities of discounting with the Bank of England. The disastrous condition in which a country banker issuing his own notes might have been placed by this regulation during the panic of 1857, will be seen at once when we remember that, according to the statement of the authorities of the Bank, all discounts ceased for three days in London, except at the Bank. The country banks of issue are therefore obliged to rely on their own resources; and when the aspect of the foreign exchanges, and the state of the unemployed notes in the hands of the Bank of England give warning that a season of peril may be expected, they commence realising, collecting their debts, and hoarding the Bank of England notes and coin, which by these means they have accumulated. The reason why bankers ought to look to the state of the foreign exchanges is the same reason as that on which a merchant watches the state of imports and exports as affecting the commodity in which he deals; and the banker ought to scrutinise the one as carefully and as closely as the merchant watches the other; for the foreign exchanges indicate the increasing plentifulness or scarcity of the article—money—in which the banker deals.

The theory of the Act of 1844 was, that as the exchanges fall you ought to contract the circulation in order that prices may fall, and so exportation of commodities take place, and thereby a rectification of the exchanges come about. But under the actual operation of that measure, the Bank's course is perhaps not quite so accurate a guide at all times for the country bank of issue to look to as it was certainly intended to become; because, although the foreign exchanges be in favour of this country the Bank is compelled by the Act, if there is a domestic drain, from political or whatever other causes, to restrict its issues just as severely as under an equivalent drain when it is the result of an adverse foreign exchange. The Act prescribes no different rule for the Bank to follow when there is an abstraction of bullion from its coffers because at that time it is profitable to send gold abroad, and when there is an abstraction of bullion during periods when it does not pay to send gold abroad, the cause being different in the two cases though the result is the same. The Act of 1844 is said to have produced substantial benefits in causing much greater caution in bankers generally in the management of their business. The limitation of the issues is also stated to be a valuable result of the Act; but the last seems to be of the less importance if it be conceded to the present opinion of all the best authorities, both in and out of parliament, that it is quite impossible for a banker to increase permanently his issue, that is, to keep out in the hands of the people of the district over which his notes circulate and pass as money, a larger quantity than the habits and wants of the district require for their daily transactions. In fact, experience teaches a note-issuing banker this lesson the moment he attempts to increase his issue: for instance, if he makes an advance or loan of 1000*l.* upon security, by handing out one of his 1000*l.* notes, in the expectation that he shall enjoy the interest upon that note for a lengthened period, if that amount of money is in excess of the wants of the district, the effect is that, very shortly, that note or notes in the aggregate of the same amount, are brought in for payment in gold, and he finds that where he meant only to make a profit upon his credit, he is obliged to part with his capital, and the transaction turns out not to be of a character to induce a repetition of it. Usually, however, the issuing bodies throughout the country have afforded to them, by the operation of the Act of 1844, and in the weekly returns of the Bank of England published in the 'London Gazette,' some index of the probable state of the money market: they are in the habit of regarding the reserve of unemployed notes in the Bank of England, as shown in those returns, to indicate the power of the Bank to afford accommodation by discount or loan on securities; and so to infer whether it is safe or not for themselves to give much or little accommodation to their own customers: and this before 1844 there was no equal means of ascertaining.

As regards the limitation of issues the practical operation of the statute is, to keep the amount really issued considerably below the maximum permitted. At the times of fairs, and the periods when farmers' rents are usually paid, and other special seasons, there is always a greater demand for the notes current in the district than is usual; now it is not always easy for a banker at these times to keep the amount of notes, that are sent into circulation, within the specific limit of the Act, and the consequence often is that the fear of incurring the penalty above mentioned, which attaches for exceeding his legal issue, causes the banker, in the last week of the four, to pay as much as possible in Bank of England notes, or in gold, in order to keep within his maximum. This fear, therefore, also causes him to keep by him a greater quantity of gold and Bank of England notes, than otherwise probably he would feel to be necessary.

In opposition to the plan of a single central bank of issue for the whole kingdom, it is alleged that the public would suffer, inasmuch as the alteration would subtract from the private banker's means of affording accommodation to those who were in the habit of regarding his notes as money, and finding they could use them as money. This further inconvenience would occur, it is said, to retail dealers and others, in case the circulation were exclusively composed of copper and silver, and, as to the larger sums, of gold and Bank of England notes; there would be no obligation on a banker or any one to give gold for notes; the consequence of that would be that a banker (and this is the case it is stated at present in some districts so circumstanced) will not give sovereigns in exchange for a Bank of England note without the charge of sixpence or more. ('Evidence before Committee on Banks,' &c., 1858, Q. 1328.) There appears to be enough of hardship in this state of things, to make it deserving of consideration with a view to remedy.

A desire has been frequently expressed by English writers on political economy, that Parliament should make it obligatory on banks of issue to lodge with the government, securities to the amount of their issue of notes, as we have described is done in the United States; and the ground on which this requirement is principally rested, is the hardship on the traders and others in the districts in which any particular banker's notes are in circulation, of being practically obliged to receive those notes from their debtors, whilst they have no guarantee whatever that they may not turn out to be worthless. They are, therefore, it is argued, entitled to have the assurance of that which is put upon them for money being really what it assumes to be, so that in case the bank fails, they should be secured from loss, and their case is distinguished from that of the depositor in the bank, and they are said to be justly entitled to a priority over him, and to have their claims paid in full, whatever may be his fate, because he is a volunteer; in coming forward to place his money in the banker's hands he acts quite spontaneously, and without coercion or obligation of any kind. The country bankers, however, are understood to consider that it would be better for them to abandon issuing altogether, than to go on issuing, subject to the deposit of the same amount of security with the government. At present, they look upon their capital as under their own control; generally, it is true, invested in government securities, but always saleable at the price they choose, and to be dealt with at their own will; but if they impounded this capital with the government, it would be beyond their control, and they would not feel secure of getting it out again when it was wanted. Practically, it would amount to paying the notes in advance, by the security given, whilst at the same time, there must be an amount of cash kept in reserve to pay them over the counter when presented at the bank, besides making provision for paying them in London. There would, in fact, be three provisions to be made for the payment of the notes instead of two, as at present is the practice.

As regards persons who commence banking now, in a neighbourhood where there is a bank of issue already established, it is manifest they start under great disadvantages; for the bank of issue has the means of giving accommodation to its customers which are afforded by its deposits, plus its circulation; but the others have only the means which their deposits afford, supposing each bank to follow the rule already stated, of investing the capital of the concern in government securities. In order to obviate the injustice which it is said arises in this way from the operation of the existing law the theory of free trade in banking has been started: the right of issuing bank notes or promises to pay, it is urged, ought to be left entirely unfettered; for country Bank notes are on the same footing in principle as cheques and bills of exchange, and the power of issuing them, consistency requires should be as free as that of issuing cheques or bills of exchange. Now, when the Bank of England begins to restrict its advances, in order to avoid the issue of more notes, as far as possible the country bankers, even the most powerful houses will begin to hoard Bank of England notes, in order to be prepared for any pressure which may come upon them; the consequence is immediately observed to be a large increase in the amount of the bills of exchange, which are always in circulation, and this increase is made in order to supply the void in the currency, which is occasioned by the Bank of England diminishing the frequency of its discounts and loans, and so withholding its usual supplies of notes to the mercantile world. It would seem, therefore, that such cases present quite clearly the fact, that bills of exchange form a part of the currency, and in truth, the experience of large traders and bankers is, that in ordinary times when confidence exists, the vast majority of the commercial payments are made by means of cheques and bills of exchange. These instruments, therefore, form part of the currency: for if they were put down, the value they represent must necessarily be represented by coin or Bank of England notes. What then, it is asked, can be the justice of limiting and fettering one portion of the paper currency when you leave wholly free two other parts of it, in the whole representing immense amounts of money; and why does not the reason assigned for limiting the issue of banker's notes, namely, that when unlimited, the issue of them operates unfavourably on the currency and in trade, equally apply to the other two cases? But this question must be left to the reader's investigation, with the remark that the operation of bills of exchange and cheques on the currency, certainly has not as yet received the notice, which, in the opinion of competent authorities on these matters, it deserves.

It does not seem possible to lay down a rule in regard to the amount of reserve which a banker issuing notes ought to keep by him in order to be safe, both as regards the claims of the note-holders and the depositors: the state of the money market at the time, and the nature of the business or occupation in which the population of the district in which the Bank is, is engaged, are matters which enter largely into the question. In times of complete quiet and confidence, it may be possible to go on, for a period, almost without any reserve at all; especially, for a house of large connections and numerous customers; because in such cases, it is found that the payments in and the payments out nearly balance each other every day. Again, a banker, carrying on business in a great centre of industry, whose customers are manufacturers, merchants, and tradesmen, and where there are not unlikely to be sudden demands to considerable extents made upon him, is bound to keep much more cash or Bank notes in hand than would be necessary in general, if he were banking in an agricultural district.

With respect to the payment of interest upon deposits, this is very seldom done by private bankers in London and the neighbourhood; the system is quite exceptional as regards private bankers in that locality: in the country, especially in the North of England, it is not so unusual.

Banking Copartnerships.—This description of banks, which is frequently but improperly confounded with joint-stock banking companies—bodies with very different attributes, characteristics, and powers—arose out of a statutory enactment, 7 Geo. IV. c. 46. A banking copartnership is also perfectly distinguishable from an ordinary banking partnership. By the combined operation of that statute and the statute 20 & 21 Vict. c. 49, s. 12, these banking copartnerships may now be erected, consisting of ten or fewer partners. Every member is liable for all the debts of the copartnership, whether he be a member when the debt was incurred, or whether he only became so after it was incurred, but before it is satisfied. In words, therefore, the Act considerably enlarges the responsibility of a member of one of these copartnerships, beyond what he would have lain under as a member of an ordinary partnership; but, in practice, the difficulty, expense, and delay of realising the intended boon to the creditor is found to make it of little avail. These copartnerships are empowered and must sue and be sued in the name of a person whom each of them is bound to appoint, and who is called the public officer of the copartnership: and the creditor, having brought his action against such public officer and obtained judgment, sues out execution against any existing member or members: if these executions are ineffectual, he may issue execution against any persons who were members at the time the contract was entered into; secondly, against any persons who were members at any time before such contract was executed; thirdly, against any persons who were members at the time the judgment was obtained: provided only, that execution cannot issue against any of the persons designated in these three classes, if three years have elapsed. Such of these bodies as were issuing their own notes on 6th May, 1844, may make their notes or bills of exchange payable in London by their agent, or may draw any bill of exchange or note payable on demand or otherwise in London, for any less amount than 50*l.* (3 & 4 Will. IV. c. 83, s. 2). These bodies are also allowed to carry on the business of banking in London or within sixty-five miles, provided they do not borrow, owe, or take up in England any sum on their bills or notes payable on demand or at any less time than six months from the borrowing, during the continuance of the privileges of the Bank of England (3 & 4 Will. IV. c. 98, s. 3); and the acceptance of a customer's bill at less than six months' date, on account of a balance in favour of the customer, is a borrowing in point of law forbidden by the statute. The average date of bills drawn in this country by traders or by bankers in this country is within three months, except the bills of the manufacturing districts: this enactment therefore has an extensive operation. These bodies are obliged to make an annual return of the names, &c., of all their members, verified on oath; also returns of persons newly becoming members, persons ceasing to be members, &c.; and it is most important for every member to see that these returns are properly made, because upon their accuracy may often turn the question of the liability or non-liability of a shareholder, when a judgment has been obtained against the company. The internal concerns of these bodies are commonly regulated by what is called a deed of settlement, to which all the partners are parties; their affairs are superintended by directors, but the real effective officer, in truth the banker, is usually called the manager. The capital is usually divided into shares, which are transferable commonly, under the restriction that the consent of the directors shall be a requisite to the transfer. Hence the purchase-money of a share can only be safely paid over to the vendor of the share, *after* the transfer has been fully completed.

It is extremely important for directors to be at all times aware of the transactions of the copartnership: it has been found to be far too much the practice to leave everything to the manager, who, in that state of things, by want of skill or knowledge or foresight, may involve the concern to ruinous extents. On the other hand, directors may incur heavy responsibilities by travelling out of the strict line of their duty as bankers: thus, where some of the directors of one of these bodies, by reason of unauthorised speculations in shipping, &c., and of a fraudulent transaction by deed of arrangement with a debtor of the copartnership, had involved it in losses, so that the copartnership was insolvent and ceased to carry on business, it was considered that the public officer might, notwithstanding that the body was in a state of suspended vitality, recover from these directors the amounts of the losses incurred through their misconduct; the sums recovered to be applied for the liquidation of the claims upon the copartnership. Directors cannot bind the shareholders severally by any instrument or writing which they may utter: thus, "We for ourselves and the other shareholders of the company jointly and severally promise to pay," signed by directors, is a document of no validity to bind the shareholders individually; though such a document appearing on the face of it to be intended to bind the copartnership, would have that effect, provided the directors signing it were authorised to sign promissory notes.

We have mentioned instances in illustration of the strictness with which the law enforces, against private bankers, the rules it lays down: these bodies are not less strictly dealt with: If a manager of a branch, wholly without the knowledge of the directors or any member of the copartnership, by fraud or circumvention of any kind, deceives a customer of the bank who acts in reliance on his position as manager of the bank, and loss ensues to the customer, the copartnership must make it good. If a body of this class, in acknowledgment of money deposited with them by a customer, gives an accountable receipt signed by a clerk, the course of dealing being that the parties to whom such receipts were given returned them to the Bank once a year to be cancelled, when they were paid off, or allowed the interest for the past year, and took fresh receipts in the room of those delivered up; and after the death of a customer, and pending a contest for the administration of his estate, the receipt comes into the hands of a stranger, who fraudulently obtains payment for it at the Bank, when the receipt was given up and cancelled by tearing off the signature, still the courts of equity hold that the company must pay over again to the real owner of the receipt.

These bodies, as we have observed, must not be confounded with ordinary partnerships. The essential distinction between a banking copartnership, on a large scale, and an ordinary common law trading partnership, consists in the power and privilege which, by the provisions of the deed of settlement of the former, are given to a proprietor to retire and withdraw his capital from the concern, without a dissolution of the partnership, by transferring his shares. This power and privilege constitute very main inducements to the investment of capital in such concerns, and thereby enable the society, or partnership, to raise a capital and carry on transactions, which it would be impracticable to raise or carry on upon the basis of an ordinary mercantile partnership. The consequences which, as between a shareholder and the company, arise, by operation of law alone, upon a transfer of shares, cannot, therefore, be inferred from those which attach upon the dissolution of an ordinary partnership. The consequences arising upon a transfer of shares must be sought for in the provisions of the deed of settlement, or in some rule of law not repugnant to those provisions. (See the law stated, Grant's 'Law of Banking,' &c.)

Joint-Stock Companies are regulated by an Act of 1844, 7 & 8 Vict., c. 113, according to which the mode of becoming a Joint-Stock Banking Company is the following:—The persons who wish to be formed into such a company are to petition the Queen in council, and on the report of the Board of Trade that the statutory requirements have been complied with, a charter will be granted: then a deed of settlement is to be executed, containing a number of provisions set out in s. 4 of the statute (which still continue to be law, with this exception, that now by a subsequent statute, 19 & 20 Vict., c. 100, the re-election of retiring directors is permitted), which deed must be executed by the holders of at least one-half of the shares into which the capital of the company is divided. But the liability of the shareholders in this class of joint-stock banks is not to be limited (we shall speak presently of the new legislation permitting the establishment of joint-stock banking companies with limited liability of shareholders); and actions may be brought by, or against, the company or shareholders reciprocally, and every judgment against the company being enforcible against it, and under certain restrictions prescribed in the first-mentioned statute, against shareholders and former shareholders, of which the effect is, that a shareholder is not liable to be sued upon the dealings, covenants, and undertakings of the company; he is only liable upon a judgment against the company. If a judgment is obtained against the company, and execution against it proves unproductive, then by certain legal processes execution may be had against any shareholder, and in the event of *that* proving unavailable to realise the sum due, the creditor may proceed to execution against any person who was a shareholder at the time the cause of action arose, with the limitation of three years, and a shareholder who has been so obliged to pay a debt of the company may be reimbursed either out of the assets of the company or by contribution from the other shareholders. It is necessary also, that the body of persons who wish to be formed into one of these companies should be provisionally registered within three months after the grant of the charter; and before the company shall begin business a memorial is to be made out, setting forth the title of the company, the names and places of abode of all the members and of every director and manager, or other like officers, and the name or firm of every bank established by the company, and the name of every town or place where the business shall be carried on. This is to be repeated every year as long as they carry on business as bankers, and the memorial is to be delivered to the Inland Revenue Office, where it is to be registered, &c. Also a printed list of the registered names and places of abode is to be made out from time to time, and kept in a conspicuous place in the company's principal place of business. A like memorial is also to be made out and delivered to the above-mentioned Board, containing the same particulars of every new director, manager, or other like officer, and the names of all persons who have become members, either in addition to, or instead of, any former members; and the name of every new town in which the company carry on business, and the names of all who have ceased to be members; and such farther account is to be registered, &c., as before. All these memorials are to be signed by the manager, or one of the directors, and verified by his declaration before a magistrate, &c.; and the persons whose names appear at any time in the then last delivered memorial shall be the existing shareholders, so that a person whose name is in the memorial is liable as a shareholder, although the memorial may not have been framed in all respects in the prescribed form. These companies are also required to make the returns required by the statute 7 & 8 Vict., c. 32, s. 21, to be made by every banker in England on the 1st of January, or within fifteen days after, in every year, under a penalty of 50*l.*

The capital stock of a joint-stock banking company under this statute 7 & 8 Vict. c. 113, is in no case to be less than 100,000*l.*, and the shares are not to be less than 100*l.* each, and every deed of settlement must contain specific provisions for preventing the company from purchasing any of the shares or making advances of money, to any person, on the security of shares. In general, there are no means by which a shareholder can be enabled to withdraw from the concern, except he can find some one who will purchase his share, and it is actually transferred to such person. No share can be transferred until all sums due for calls upon it, and upon every other share which the owner of it holds, shall have been paid. From time to time the directors may make such calls on the shareholders in respect of the amount of capital stock respectively subscribed by them, as the directors shall think fit; and, besides being liable to pay calls by way of action, shareholders are liable to forfeit their shares, by leaving calls unpaid, if the directors, at any time after six calendar months from the day appointed for the payment of such calls, declare them to be so forfeited: the shareholders still remaining liable for the calls due before the forfeiture.

The deed of settlement or partnership must contain specific provisions for the management of the affairs of the Bank and the election and qualification of the directors. Any one of the directors is empowered to sign bills of exchange or promissory notes, made, accepted, or endorsed on behalf of the company, provided it be therein expressed to be so made, &c. by him on behalf of the company.

The deed of settlement ought to contain provisions adapted to prevent any declaration of dividends on the capital by the directors, without due regard to the actual state of the company's affairs. The liability incurred by directors, who declare and divide dividends when the profits made by the company do not authorise their doing so, is very heavy. (See 19 & 20 Vict. c. 47, s. 3, compared with 20 & 21 Vict. c. 49, s. 18. See also Grant's 'Law of Banking,' &c., p. 594; 19 & 20 Vict. c. 47, s. 14; 20 & 21 Vict. c. 49, s. 18.) It is no excuse for directors so declaring dividends when the concern is not in such a state as to admit of it, that they did not act under the influence of a desire to pocket the dividends on their own shares, but with a desire of representing the affairs of the Bank to be in a prosperous condition, so as to attract an increase of custom, and to raise the value of the shares, and stimulate the demand in the market for them.

A manager, or other officer, to perform the duties of manager, must be appointed in all cases.

The deed of settlement must contain provisions for the yearly audit of the accounts by two or more auditors, chosen at a general meeting of the shareholders, and not being directors: also, provisions for the publication, once at least in every month, of the assets and liabilities of the Bank; and for the yearly communication to every shareholder of the auditor's report, of a balance sheet and profit and loss account. As regards the requirement of the law, that these banks should make periodical statements of their affairs, experience has shown these documents to be capable, by dexterous management, of conveying the most fallacious impressions of the real state of things: by the simple expedient, for instance, of not writing off bad debts, and of considering those to be good engagements which, though perhaps not wholly without value, may be utterly unavailing as banking securities, a fair statement of assets may be presented on the balance-sheet, while in truth a company may be in any thing but a prosperous condition. Such a process, it must be remembered, is always available, almost without any risk of immediate detection; indeed, to a certain extent, it may be a question of opinion when to write off a debt as bad or irrecoverably lost; but still the public, who confide in these accounts, have no available means of ascertaining how far the statements in the periodical balance-sheets or states of liabilities and assets have been framed with judgment and honesty, and how far they are designedly put forward with a view of attracting depositors, keeping up the price of the shares in the market, and generally of deceiving and overreaching. The accounts given, it has been alleged, are not sufficiently explicit: to be serviceable, so as to enable persons consulting them to get a practical insight into the nature of the business, they ought to go into details to some extent, not inconsistent with the secrecy in regard to individual transactions, which is indispensable in banking. For instance, it has been urged that a material improvement in the accounts would be, that they should state the amount of over-due bills held by the company at the time of making out the account, together with the sum they were estimated to be likely to realise. Still, in the opinion of experienced bankers no form of account could be framed, with due regard to secrecy, which would enable the shareholders of a bank in which there was anything going wrong to discover where the fault lay, or to put any check on any misconduct or mismanagement of the directors. In the opinion of the best authorities on the subject, you must in the end trust to the honour and integrity and capacity of the directors and manager. But if the periodically published statements are fallacious, what is the case of the audit? How can it be possible to accomplish an effectual audit of the affairs and transactions of bodies of such a magnitude of business as is done by some of the London Joint Stock Banks, some of which hold from 8 to 13 millions sterling of deposits? In general it is probable all that auditors do, indeed all that they can do, is to examine the balance sheet laid before them by the directors, with the help of such vouchers as they can procure: they can merely vouch for the fact of the balance sheet being correct on the data supplied to them. But an effective audit of a bank is something very different from this; it ought to include a full view of the real position of the affairs. Now in taking an account of the assets of a bank, the highest judgment is requisite, founded on acquaintance with the principles of the art of banking. A bill of exchange is either the very best or the worst asset of a bank, and it depends on the judgment of the person examining the asset whether he counts it as good or bad. For an auditor to give a full account of the actual state of a bank, he must value every security; and how is this to be done in cases, for instance, of securities given by persons unknown beyond the district over which the operations of the Bank extend, without a local knowledge of the parties in the auditor? He ought to be in a condition to follow every transaction, especially with reference to bills of exchange, which might be rediscounted at the moment of the audit and so out of the hands of the Bank, and to be able to judge of all the securities, so as to tell whether they would ultimately turn out an asset of the Bank or a claim upon it; in fact, he must acquire a knowledge of all the affairs of the concern as intimate as that possessed by the directors, or the manager himself, before he would be able to report much more with certainty than whether the book-keeping was right, and that the balances were right, on a comparison of the entries with the vouchers. On the whole, there appear to be insuperable objections in the way of obtaining a really effective audit of the affairs of joint-stock banks.

Very material changes have taken place in this country, both with respect to the increased practice of opening accounts with bankers as current accounts on which to draw and pay in, and also in the new practice of deposit accounts on which money is paid into the joint-stock banks, to be retained by them for a short period, after which interest is paid upon it; and on the other hand it can be withdrawn at a short notice, or in some cases at pleasure. The effect of this system of paying interest on deposits has been to attract to these banks an immense aggregate of small sums, often of sums as small as 10*l.* each, which formerly were most probably hoarded. This seems to be a fair and just inference, because from the nature of the case the small sums which are said to form the majority of the deposit accounts of joint-stock banks, could not have formed the subject of accounts in the old banks, and therefore could not have been taken from the private banks in order to be transferred to the joint-stock banks, and the published accounts of the savings' banks show no diminution of the deposits there; so the result seems to be that the joint-stock banks, by the advantages which they hold out, have succeeded in drawing together vast numbers of small sums which previously were hoarded, and which are now placed in the hands of these companies as a kind of investment, where a moderate interest can be enjoyed without the trouble and expense, and sometimes the loss, with which the conversion of other securities is attended. The advantage to the community of this system is stated to be, its tendency to foster habits of prudence and self-denial in the classes of small tradesmen, artisans, mechanics, servants, &c., by furnishing them with the means of obtaining interest for whatever they may save. The disadvantage arises from the result to which the system has been successful; this it is said consists in the peril arising from such enormous masses of money being held at call, or nearly so, and bearing interest, a posture of affairs which compels the joint-stock banks, in order to make a profit, to find instant employment of the money, which necessarily must be effected by discounting bills, of an inferior character to those which they would have dealt with, had the pressure on them to turn their deposits to advantage been less stringent and overpowering. The system is accordingly looked upon with disfavour and apprehension by very high authorities in banking. The following is a statement of the amount of deposits in the London joint-stock banks on the 31st of December, 1857, except in the cases of the Union and the Commercial banks, the accounts in which are made up to the 30th of June.

1857.	
London and Westminster	£13,889,021
London Joint-Stock	10,737,589
Union	10,874,640
Commercial	936,724
London and County	3,533,425
City	1,388,933
Bank of London	1,114,846
Unity	117,380

There is no attempt, however, to deny that it was in fact by means of the large deposits made by the joint-stock banks, in the Bank of England, during the crisis of 1857, that the Bank of England was, in part, enabled to make the advances which it did make for the accommodation of the commercial body. The joint-stock banks, in order to be ready to meet the claims which their depositors might make upon them, instead of employing those deposits by discounting with them, for others than their customers, preferred, for the time, to deposit their reserves, beyond what they kept in their own tills, with the Bank, whence any sums they might want might be withdrawn at pleasure, and so were amply prepared for the crisis. The Bank of England, on the other hand, employed a large portion of these deposits in discounting the bills and advancing upon the securities that were brought to it, by houses requiring accommodation. The joint-stock banks may thus be said to have increased the power of the Bank of England to grant accommodation to trade in times of stagnation and collapse of confidence; first, by drawing within the sphere of banking operations large aggregates of moneys, which formerly never found their way into banks at all, and then by opening accounts with the Bank of England and placing there their reserves, at seasons when they might be turned to the above purpose.

The interest allowed to their depositors by the London joint-stock banks was till lately governed by the Bank rate of the day, being mostly one per cent lower than that rate; now however, they do not observe that rule, but pay more nearly according to the rate of interest which rules in the general money market.

As to the profits of joint-stock banks, it is necessary to distinguish carefully between profits and dividends. The profits are made on the whole funds that the bank employs in making loans, investing in securities, &c.; the dividends are the rateable division at so much per cent. upon the paid-up capital of the shares. Therefore, where the funds employed as above are large, a small per centage of profit on them may supply a large dividend per cent. on the paid-up capital. This distinction, obvious though it be, has frequently been overlooked, and it is asked, when joint-stock banks announce dividends of 18 or 20 per cent., how it is possible to account for such *profits?* An example will show this clearly. A joint-stock bank paying 20 per cent. dividend had paid-up capital of 600,000*l.*, and on 1st January, 1858, its deposits were 10,700,000*l.* Then, supposing its capital to be invested in government securities paying 3 per cent. per annum interest, and an interest of only 1 per cent. per annum to be derived from its deposits, the two sums thus produced make a total which accounts for the dividend.

The practice of rediscounting has been inveighed against with severity, but perhaps without sufficient grounds for that severity of censure with which it is often spoken of. It is in fact one means of transferring the surplus capital of one district to another where it is wanted; thus a bank in Norwich sends up the money for which it can find no profitable employment in its own district, to an agent or a bill-broker in London, with whom it places the money at call and receives interest. Another bank, in a district where there is a demand for money, say Manchester, sends up the bills of exchange that it has discounted, to the same bill-broker in London, who rediscounts the bill with the money he has received from the bank at Norwich, and thus the money is transferred from Norwich to Manchester. In fact, as experience shows, any firm, however prudently conducted, may find it convenient under extraordinary circumstances of pressure, to change, in this way, some of its first-class bills. But, however this may be, the London joint-stock bankers, it seems, never rediscount. (Evidence before Committee on the Bank Act, &c., 1858, Q. 1164, 2245; and see 3 Hansard's 'Debates,' vol. 95, col. 392.) It is true the system may be abused, and instances have occurred where provincial joint-stock banks have discounted paper which they sent up for rediscount in London, and which was so rediscounted solely on the credit of the Bank's endorsement, the other names on it being those of persons of no credit at all. This system of rediscounting is quite distinguishable from lending money upon the security of bills deposited with the lender; a practice to which there seems to be no objection entertained by any one, and which a bank may follow with perfect security. When a banker lends money on the security of bills which the borrower deposits with him, returning to the latter the bills when he recalls the loan, that is no more a rediscount than lending money on the deposit of Consols is.

Joint-Stock Banking Companies (*limited*).—Banking companies on the joint-stock principle, but with liability of the shareholders for the debts incurred by the companies limited to the extent of those shares, are now permitted to be established under the statute 21 & 22 Vict. c. 91.

Banking in Ireland.—In 1783, a national bank, called the Bank of Ireland, was established by charter in Ireland, with similar privileges to those enjoyed by the Bank of England under the Act of 1708. The management is vested in a governor, deputy-governor, and fifteen directors, of whom five go out annually; the election is by a "house list," which is usually adopted by the proprietors.

In 1845 was passed the Act (8 & 9 Vict. c. 37) which now regulates the issue of bank notes of the Bank of Ireland, and the issue of private bankers' notes, &c., by regulations closely analogous to those contained in the statute 7 & 8 Vict. c. 32, relative to the same subjects in England, the great difference being, that the Bank of Ireland note is not made a legal tender in Ireland.

The capital of the Bank of Ireland is 3,000,000*l.* Irish, being about 2,800,000*l.* English, of which 2,630,769*l.* English is lent to the government. The dividend paid in 1857 was 12¼ per cent. The "rest," which is formed from accumulated profits, is 1,040,000*l.* Thus, about 1,200,000*l.* represents the actual trading capital of the corporation. As regards the issue of notes, that privilege was granted to the Bank in consideration of the loan advanced to government, and the issue is 3,738,000*l.*, of which 1,300,000*l.* consists of notes under 5*l.* each. The Bank has invested in government securities to the extent of 2,900,000*l.*; they are expressly prohibited from investing in mortgages. The accounts of the Bank are published in the 'Gazette,' as those of the Bank of England are. The other issuing banks in Ireland are: the Provincial Bank of Ireland (founded in 1825), the National Bank of Ireland, the Belfast Banking Company, the Ulster Banking Company, and the Northern Banking Company. The Bank of Ireland discounts bills of exchange for any person in trade who is known at the office of the secretary of the bank; and they discount at rates varying with those of the Bank of England, so as to avoid making it profitable for persons to send bills to Ireland to be discounted in consequence of the rate being materially lower than that at the Bank of England; and generally, since the removal of the prohibition in the charter from taking more than 5 per cent. interest, and the abolition of the Usury Laws, the rate of interest has been higher than before. The other banks are governed a great deal by the Bank of Ireland in this respect; and when the rate in Ireland is higher than at the Bank of England, bills are sent to England for discount. From one-fourth to one-fifth of the deposits is what the Bank of Ireland usually considers, in ordinary times, to be the proportion to keep in its coffers as a reserve.

The system of clearing in Dublin is the following. An amount of 370,000*l.* of Exchequer bonds is held, in certain proportions, by the different banks; clerks from those banks meet every evening, and where the balance of notes of one bank is above that of the other, Exchequer bonds are given in lieu. If the quantity of Exchequer bonds be thus reduced below two-thirds of the amount which ought to upon the dissolution of an ordinary partnership. The consequences arising upon a transfer of shares must be sought for in the provisions of the deed of settlement, or in some rule of law not repugnant to those provisions. (See the law stated, Grant's 'Law of Banking,' &c.)

Joint-Stock Companies are regulated by an Act of 1844, 7 & 8 Vict., c. 113, according to which the mode of becoming a Joint-Stock Banking Company is the following:—The persons who wish to be formed into such a company are to petition the Queen in council, and on the report of the Board of Trade that the statutory requirements have been complied with, a charter will be granted: then a deed of settlement is to be executed, containing a number of provisions set out in s. 4 of the statute (which still continue to be law, with this exception, that now by a subsequent statute, 19 & 20 Vict., c. 100, the re-election of retiring directors is permitted), which deed must be executed by the holders of at least one-half of the shares into which the capital of the company is divided. But the liability of the shareholders in this class of joint-stock banks is not to be limited (we shall speak presently of the new legislation permitting the establishment of joint-stock banking companies with limited liability of shareholders); and actions may be brought by, or against, the company or shareholders reciprocally, and every judgment against the company being enforcible against it, and under certain restrictions prescribed in the first-mentioned statute, against shareholders and former shareholders, of which the effect is, that a shareholder is not liable to be sued upon the dealings, covenants, and undertakings of the company; he is only liable upon a judgment against the company. If a judgment is obtained against the company, and execution against it proves unproductive, then by certain legal processes execution may be had against any shareholder, and in the event of *that* proving unavailable to realise the sum due, the creditor may proceed to execution against any person who was a shareholder at the time the cause of action arose, with the limitation of three years, and a shareholder who has been so obliged to pay a debt of the company may be reimbursed either out of the assets of the company or by contribution from the other shareholders. It is necessary also, that the body of persons who wish to be formed into one of these companies should be provisionally registered within three months after the grant of the charter; and before the company shall begin business a memorial is to be made out, setting forth the title of the company, the names and places of abode of all the members and of every director and manager, or other like officers, and the name or firm of every bank established by the company, and the name of every town or place where the business shall be carried on. This is to be repeated every year as long as they carry on business as bankers, and the memorial is to be delivered to the Inland Revenue Office, where it is to be registered, &c. Also a printed list of the registered names and places of abode is to be made out from time to time, and kept in a conspicuous place in the company's principal place of business. A like memorial is also to be made out and delivered to the above-mentioned Board, containing the same particulars of every new director, manager, or other like officer, and the names of all persons who have become members, either in addition to, or instead of, any former members; and the name of every new town in which the company carry on business, and the names of all who have ceased to be members; and such farther account is to be registered, &c., as before. All these memorials are to be signed by the manager, or one of the directors, and verified by his declaration before a magistrate, &c.; and the persons whose names appear at any time in the then last delivered memorial shall be the existing shareholders, so that a person whose name is in the memorial is liable as a shareholder, although the memorial may not have been framed in all respects in the prescribed form. These companies are also required to make the returns required by the statute 7 & 8 Vict., c. 32, s. 21, to be made by every banker in England on the 1st of January, or within fifteen days after, in every year, under a penalty of 50*l*.

The capital stock of a joint-stock banking company under this statute 7 & 8 Vict. c. 113, is in no case to be less than 100,000*l*., and the shares are not to be less than 100*l*. each, and every deed of settlement must contain specific provisions for preventing the company from purchasing any of the shares or making advances of money, to any person, on the security of shares. In general, there are no means by which a shareholder can be enabled to withdraw from the concern, except he can find some one who will purchase his share, and it is actually transferred to such person. No share can be transferred until all sums due for calls upon it, and upon every other share which the owner of it holds, shall have been paid. From time to time the directors may make such calls on the shareholders in respect of the amount of capital stock respectively subscribed by them, as the directors shall think fit; and, besides being liable to pay calls by way of action, shareholders are liable to forfeit their shares, by leaving calls unpaid, if the directors, at any time after six calendar months from the day appointed for the payment of such calls, declare them to be so forfeited: the shareholders still remaining liable for the calls due before the forfeiture.

The deed of settlement or partnership must contain specific provisions for the management of the affairs of the Bank and the election and qualification of the directors. Any one of the directors is empowered to sign bills of exchange or promissory notes, made, accepted, or endorsed on behalf of the company, provided it be therein expressed to be so made, &c. by him on behalf of the company.

The deed of settlement ought to contain provisions adapted to prevent any declaration of dividends on the capital by the directors, without due regard to the actual state of the company's affairs. The liability incurred by directors, who declare and divide dividends when the profits made by the company do not authorise their doing so, is very heavy. (See 19 & 20 Vict. c. 47, s. 3, compared with 20 & 21 Vict. c. 49, s. 18. See also Grant's 'Law of Banking,' &c., p. 594; 19 & 20 Vict. c. 47, s. 14; 20 & 21 Vict. c. 49, s. 18.) It is no excuse for directors so declaring dividends when the concern is not in such a state as to admit of it, that they did not act under the influence of a desire to pocket the dividends on their own shares, but with a desire of representing the affairs of the Bank to be in a prosperous condition, so as to attract an increase of custom, and to raise the value of the shares, and stimulate the demand in the market for them.

A manager, or other officer, to perform the duties of manager, must be appointed in all cases.

The deed of settlement must contain provisions for the yearly audit of the accounts by two or more auditors, chosen at a general meeting of the shareholders, and not being directors: also, provisions for the publication, once at least in every month, of the assets and liabilities of the Bank; and for the yearly communication to every shareholder of the auditor's report, of a balance sheet and profit and loss account. As regards the requirement of the law, that these banks should make periodical statements of their affairs, experience has shown these documents to be capable, by dexterous management, of conveying the most fallacious impressions of the real state of things: by the simple expedient, for instance, of not writing off bad debts, and of considering those to be good engagements which, though perhaps not wholly without value, may be utterly unavailing as banking securities, a fair statement of assets may be presented on the balance-sheet, while in truth a company may be in any thing but a prosperous condition. Such a process, it must be remembered, is always available, almost without any risk of immediate detection; indeed, to a certain extent, it may be a question of opinion when to write off a debt as bad or irrecoverably lost; but still the public, who confide in these accounts, have no available means of ascertaining how far the statements in the periodical balance-sheets or states of liabilities and assets have been framed with judgment and honesty, and how far they are designedly put forward with a view of attracting depositors, keeping up the price of the shares in the market, and generally of deceiving and overreaching. The accounts given, it has been alleged, are not sufficiently explicit: to be serviceable, so as to enable persons consulting them to get a practical insight into the nature of the business, they ought to go into details to some extent, not inconsistent with the secrecy in regard to individual transactions, which is indispensable in banking. For instance, it has been urged that a material improvement in the accounts would be, that they should state the amount of over-due bills held by the company at the time of making out the account, together with the sum they were estimated to be likely to realise. Still, in the opinion of experienced bankers no form of account could be framed, with due regard to secrecy, which would enable the shareholders of a bank in which there was anything going wrong to discover where the fault lay, or to put any check on any misconduct or mismanagement of the directors. In the opinion of the best authorities on the subject, you must in the end trust to the honour and integrity and capacity of the directors and manager. But if the periodically published statements are fallacious, what is the case of the audit? How can it be possible to accomplish an effectual audit of the affairs and transactions of bodies of such a magnitude of business as is done by some of the London Joint Stock Banks, some of which hold from 8 to 13 millions sterling of deposits? In general it is probable all that auditors do, indeed all that they can do, is to examine the balance sheet laid before them by the directors, with the help of such vouchers as they can procure: they can merely vouch for the fact of the balance sheet being correct on the data supplied to them. But an effective audit of a bank is something very different from this; it ought to include a full view of the real position of the affairs. Now in taking an account of the assets of a bank, the highest judgment is requisite, founded on acquaintance with the principles of the art of banking. A bill of exchange is either the very best or the worst asset of a bank, and it depends on the judgment of the person examining the asset whether he counts it as good or bad. For an auditor to give a full account of the actual state of a bank, he must value every security; and how is this to be done in cases, for instance, of securities given by persons unknown beyond the district over which the operations of the Bank extend, without a local knowledge of the parties in the auditor? He ought to be in a condition to follow every transaction, especially with reference to bills of exchange, which might be rediscounted at the moment of the audit and so out of the hands of the Bank, and to be able to judge of all the securities, so as to tell whether they would ultimately turn out an asset of the Bank or a claim upon it; in fact, he must acquire a knowledge of all the affairs of the concern as intimate as that possessed by the directors, or the manager himself, before he would be able to report much more with certainty than whether the book-keeping was right, and that the balances were right, on a comparison of the entries with the vouchers. On the whole, there appear to be insuperable objections in the way of obtaining a really effective audit of the affairs of joint-stock banks.

Very material changes have taken place in this country, both with respect to the increased practice of opening accounts with bankers as current accounts on which to draw and pay in, and also in the new practice of deposit accounts on which money is paid into the joint-stock banks, to be retained by them for a short period, after which interest is paid upon it; and on the other hand it can be withdrawn at a short notice, or in some cases at pleasure. The effect of this system of paying interest on deposits has been to attract to these banks an immense aggregate of small sums, often of sums as small as 10*l.* each, which formerly were most probably hoarded. This seems to be a fair and just inference, because from the nature of the case the small sums which are said to form the majority of the deposit accounts of joint-stock banks, could not have formed the subject of accounts in the old banks, and therefore could not have been taken from the private banks in order to be transferred to the joint-stock banks, and the published accounts of the savings' banks show no diminution of the deposits there; so the result seems to be that the joint-stock banks, by the advantages which they hold out, have succeeded in drawing together vast numbers of small sums which previously were hoarded, and which are now placed in the hands of these companies as a kind of investment, where a moderate interest can be enjoyed without the trouble and expense, and sometimes the loss, with which the conversion of other securities is attended. The advantage to the community of this system is stated to be, its tendency to foster habits of prudence and self-denial in the classes of small tradesmen, artisans, mechanics, servants, &c., by furnishing them with the means of obtaining interest for whatever they may save. The disadvantage arises from the result to which the system has been successful; this it is said consists in the peril arising from such enormous masses of money being held at call, or nearly so, and bearing interest, a posture of affairs which compels the joint-stock banks, in order to make a profit, to find instant employment of the money, which necessarily must be effected by discounting bills, of an inferior character to those which they would have dealt with, had the pressure on them to turn their deposits to advantage been less stringent and overpowering. The system is accordingly looked upon with disfavour and apprehension by very high authorities in banking. The following is a statement of the amount of deposits in the London joint-stock banks on the 31st of December, 1857, except in the cases of the Union and the Commercial banks, the accounts in which are made up to the 30th of June.

1857.	
London and Westminster	£13,889,021
London Joint-Stock	10,737,589
Union	10,874,640
Commercial	936,724
London and County	3,533,425
City	1,388,933
Bank of London	1,114,846
Unity	117,380

There is no attempt, however, to deny that it was in fact by means of the large deposits made by the joint-stock banks, in the Bank of England, during the crisis of 1857, that the Bank of England was, in part, enabled to make the advances which it did make for the accommodation of the commercial body. The joint-stock banks, in order to be ready to meet the claims which their depositors might make upon them, instead of employing those deposits by discounting with them, for others than their customers, preferred, for the time, to deposit their reserves, beyond what they kept in their own tills, with the Bank, whence any sums they might want might be withdrawn at pleasure, and so were amply prepared for the crisis. The Bank of England, on the other hand, employed a large portion of these deposits in discounting the bills and advancing upon the securities that were brought to it, by houses requiring accommodation. The joint-stock banks may thus be said to have increased the power of the Bank of England to grant accommodation to trade in times of stagnation and collapse of confidence; first, by drawing within the sphere of banking operations large aggregates of moneys, which formerly never found their way into banks at all, and then by opening accounts with the Bank of England and placing there their reserves, at seasons when they might be turned to the above purpose.

The interest allowed to their depositors by the London joint-stock banks was till lately governed by the Bank rate of the day, being mostly one per cent lower than that rate; now however, they do not observe that rule, but pay more nearly according to the rate of interest which rules in the general money market.

As to the profits of joint-stock banks, it is necessary to distinguish carefully between profits and dividends. The profits are made on the whole funds that the bank employs in making loans, investing in securities, &c.; the dividends are the rateable division at so much per cent. upon the paid-up capital of the shares. Therefore, where the funds employed as above are large, a small per centage of profit on them may supply a large dividend per cent. on the paid-up capital. This distinction, obvious though it be, has frequently been overlooked, and it is asked, when joint-stock banks announce dividends of 18 or 20 per cent., how it is possible to account for such *profits?* An example will show this clearly. A joint-stock bank paying 20 per cent. dividend had paid-up capital of 600,000*l.*, and on 1st January, 1858, its deposits were 10,700,000*l.* Then, supposing its capital to be invested in government securities paying 3 per cent. per annum interest, and an interest of only 1 per cent. per annum to be derived from its deposits, the two sums thus produced make a total which accounts for the dividend.

The practice of rediscounting has been inveighed against with severity, but perhaps without sufficient grounds for that severity of censure with which it is often spoken of. It is in fact one means of transferring the surplus capital of one district to another where it is wanted; thus a bank in Norwich sends up the money for which it can find no profitable employment in its own district, to an agent or a bill-broker in London, with whom it places the money at call and receives interest. Another bank, in a district where there is a demand for money, say Manchester, sends up the bills of exchange that it has discounted, to the same bill-broker in London, who rediscounts the bill with the money he has received from the bank at Norwich, and thus the money is transferred from Norwich to Manchester. In fact, as experience shows, any firm, however prudently conducted, may find it convenient under extraordinary circumstances of pressure, to change, in this way, some of its first-class bills. But, however this may be, the London joint-stock bankers, it seems, never rediscount. (Evidence before Committee on the Bank Act, &c., 1858, Q. 1164, 2245; and see 3 Hansard's 'Debates,' vol. 95, col. 392.) It is true the system may be abused, and instances have occurred where provincial joint-stock banks have discounted paper which they sent up for rediscount in London, and which was so rediscounted solely on the credit of the Bank's endorsement, the other names on it being those of persons of no credit at all. This system of rediscounting is quite distinguishable from lending money upon the security of bills deposited with the lender; a practice to which there seems to be no objection entertained by any one, and which a bank may follow with perfect security. When a banker lends money on the security of bills which the borrower deposits with him, returning to the latter the bills when he recalls the loan, that is no more a rediscount than lending money on the deposit of Consols is.

Joint-Stock Banking Companies (limited).—Banking companies on the joint-stock principle, but with liability of the shareholders for the debts incurred by the companies limited to the extent of those shares, are now permitted to be established under the statute 21 & 22 Vict. c. 91.

Banking in Ireland.—In 1783, a national bank, called the Bank of Ireland, was established by charter in Ireland, with similar privileges to those enjoyed by the Bank of England under the Act of 1708. The management is vested in a governor, deputy-governor, and fifteen directors, of whom five go out annually; the election is by a "house list," which is usually adopted by the proprietors.

In 1845 was passed the Act (8 & 9 Vict. c. 37) which now regulates the issue of bank notes of the Bank of Ireland, and the issue of private bankers' notes, &c., by regulations closely analogous to those contained in the statute 7 & 8 Vict. c. 32, relative to the same subjects in England, the great difference being, that the Bank of Ireland note is not made a legal tender in Ireland.

The capital of the Bank of Ireland is 3,000,000*l.* Irish, being about 2,800,000*l.* English, of which 2,630,769*l.* English is lent to the government. The dividend paid in 1857 was 12½ per cent. The "rest," which is formed from accumulated profits, is 1,040,000*l.* Thus, about 1,200,000*l.* represents the actual trading capital of the corporation. As regards the issue of notes, that privilege was granted to the Bank in consideration of the loan advanced to government, and the issue is 3,738,000*l.*, of which 1,300,000*l.* consists of notes under 5*l.* each. The Bank has invested in government securities to the extent of 2,900,000*l.*; they are expressly prohibited from investing in mortgages. The accounts of the Bank are published in the 'Gazette,' as those of the Bank of England are. The other issuing banks in Ireland are: the Provincial Bank of Ireland (founded in 1825), the National Bank of Ireland, the Belfast Banking Company, the Ulster Banking Company, and the Northern Banking Company. The Bank of Ireland discounts bills of exchange for any person in trade who is known at the office of the secretary of the bank; and they discount at rates varying with those of the Bank of England, so as to avoid making it profitable for persons to send bills to Ireland to be discounted in consequence of the rate being materially lower than that at the Bank of England; and generally, since the removal of the prohibition in the charter from taking more than 5 per cent. interest, and the abolition of the Usury Laws, the rate of interest has been higher than before. The other banks are governed a great deal by the Bank of Ireland in this respect; and when the rate in Ireland is higher than at the Bank of England, bills are sent to England for discount. From one-fourth to one-fifth of the deposits is what the Bank of Ireland usually considers, in ordinary times, to be the proportion to keep in its coffers as a reserve.

The system of clearing in Dublin is the following. An amount of 370,000*l.* of Exchequer bonds is held, in certain proportions, by the different banks; clerks from those banks meet every evening, and where the balance of notes of one bank is above that of the other, Exchequer bonds are given in lieu. If the quantity of Exchequer bonds be thus reduced below two-thirds of the amount which ought to be held, the party so reducing it is obliged to purchase from some of the others, and to give a draft on London for the amount.

The country circulation of Ireland is regulated in this manner, under the Act of 1845. There is a certain amount limited in the Act, to which each bank of issue may issue notes; all issues of notes beyond that must be made against a corresponding value of bullion. The objection against making the Bank of England note a legal tender in Ireland is that, so far as Ireland is concerned, such portion of the currency as might be constituted of Bank of England notes would be practically inconvertible, unless, at any rate, the Bank of England had some branch in Ireland at which gold should be payable for the notes on demand.

All the banks of issue in Ireland issue notes under 5*l.* each. The Bank of Ireland issues 1*l.* notes and 3*l.* notes; but the circulation of 3*l.* notes is not considerable. Some of the other issuing banks issue 2*l.* notes as well as 1*l.* notes. Previously to the failure of the Tipperary Joint-stock Bank, in 1855, all panics or runs upon banks had been observed to originate with the holders of the small notes; but since that bank, which was a bank of deposit only, stopped payment, runs have commenced with the depositors. The panic of 1857, which extended all over the country, was to the greatest extent among the depositors.

The joint-stock banks are four in Dublin (some of these having branches extending over every part of the country), and three in the country. The Bank of Ireland is the only chartered bank, and has twenty-six branches. The joint-stock banks all allow interest on deposits, there being a general understanding that one shall not allow a higher rate than another, the deposits being partly held on call and in part on notice. The Bank of Ireland allows no interest on deposits. The joint-stock banks of Ireland are not obliged to publish periodical statements, showing the amount of their deposits. Usually the number of shareholders in an Irish joint-stock bank is very considerable, some of them being wealthy persons, but the greater number of them are represented to be widows, clergymen, and persons who have small sums, and are dependent on the incomes arising from them. The same change in the practice of opening accounts with a banker which has been mentioned as having been so widely manifested in England of late years, has also been observed in Ireland, and has caused large accumulations of deposits in the hands of the joint-stock bankers, and banking operations have very much increased accordingly. ('Evidence before Committee,' &c., 1858, pp. 264-287.) The law in Ireland, founded on a statute of the Irish parliament, is understood to prohibit private bankers (that is, bankers other than joint-stock bankers) from paying interest on deposits. (*Ib.* Q. 5805.)

V. *Scotch system of Banking.*—There are three incorporated public banks in Scotland: one of these, called the Bank of Scotland, was established by act of the Scottish parliament in 1695; another, called the Royal Bank of Scotland, received a royal charter in 1727; and the third, the British Linen Company, was incorporated in 1746, for the purpose of undertaking the manufacture of linen, but now operates as a banking company only; its capital is 500,000*l.* None of the Scotch banks have exclusive privileges resembling those of the Bank of England and Bank of Ireland.

The capital of the Bank of Scotland was originally 1,200,000*l.* Scots, or 100,000*l.* sterling money, divided into 1200 shares. This capital has since been augmented at different times, and now amounts to 1,500,000*l.* sterling, but of this sum only one million has been paid up by the subscribers. This bank began to establish branches in 1696, and issued notes for 1*l.* each, in 1704. It also began very early to receive deposits, for which it allowed interest; and in 1729 it introduced the plan of granting credits on cash accounts, which now forms a principal feature of the Scotch banking system.

The nature of these cash accounts consists in the Bank giving credit on loan, to the extent of a sum agreed upon, to any individual or house of business that can procure two or more persons, of undoubted credit and property, to become surety for the repayment, on demand, of the sum credited, with interest. When a person has obtained this credit, he may employ the amount in his business, paying interest only upon the sum which he actually uses, and having interest allowed to him from the day of repaying any part of the loan. These loans are advanced in the notes of the Bank, whose advantage from the system consists in the call which these credits produce for the issue of their paper, and from the opportunity which they afford for the profitable employment of part of their deposits. In order to render this part of their business as advantageous and secure as possible, it is necessary that the credits should be frequently operated upon; and if the managers of the Bank find that they are used as dead loans to produce interest only, or that the operations of the borrower are infrequent, so that the amount of notes called for is inconsiderable during the year, they will speedily put an end to the credit, it being to the interest of the Bank to keep up an active circulation of its notes.

These cash accounts are found to be very advantageous to traders, by supplying an additional capital, for the use of which they pay only in proportion to the amount of it which they employ; but they are not so generally used now as they were some time ago; the majority of them are probably for sums under 1000*l.* each.

The management of the Bank of Scotland is vested in a governor, deputy-governor, twelve ordinary and twelve extraordinary directors. They are chosen every year by the stockholders having 250*l.* of stock or upwards. The management of the various branches, which are opened in all the principal towns in Scotland, is confided to cashiers or agents.

The Royal Bank of Scotland had at first a capital of 150,000*l.*, which has since been increased to 2,000,000*l.* The system of business adopted by this establishment, and by the British Linen Company, is the same as that of the Bank of Scotland, which has already been described. These three banks are incorporated with limited liability.

The statute of 1845 (8 & 9 Vict. c. 38), containing provisions analogous to those of the Bank Charter Act of 1844, which regulated the issues of the note-issuing banks of England, regulates the Scotch paper circulation. The average of the gold circulation for 3 years previous to 1845 was under 400,000*l.*; since then the average gold circulation has been always above 1,000,000*l.* Of the paper circulation, very nearly two-thirds usually consists of notes under 5*l.* The total authorised note circulation is about 3,000,000*l.*; and for all that the banks issue above that sum they are obliged to hold sovereigns. The banks are considered not to be so strongly in favour of a continuance of the 1*l.* note circulation as they were in 1826. There appear to be no banks in Scotland which are not banks of issue.

Besides the system of cash accounts, a principal point in the Scotch banking system is the maintenance at all times of large reserves in government securities, or in cash; and particularly that there should always be a large reserve in London, where, in point of fact, all the large claims upon the Scotch banks are finally liquidated. The older banks regard as a proper reserve, a sum equal to about one-fourth or one-third of their liabilities on their notes and deposits. The Scotch banks allow a moderate rate of interest (2, 3, or 3½ per cent.) upon money deposited with them, whether upon what are called deposit receipts or on current accounts; in 1858, it was 2 per cent. The interest they charge on cash credits, or overdrawn accounts, has been 6½ or 7 per cent., in times of pressure; at present (1859) it is much lower, and is usually about 5 per cent. Since 1845 they have charged in addition one-half per cent. commission. Many of the depositors lodge their money permanently as an investment. When a deposit account is opened, a receipt for the amount is given to the depositor; if he wishes to remove it, on his presenting the receipt, the deposit is returned; or he can pay in again a portion of the sum, if he does not require the whole, when a fresh receipt for such portion is handed to him. The system of deposits removeable at a notice, the interest paid being of course higher, has not succeeded in Scotland.

Banking has for a considerable period been carried on more largely, and the habit of keeping an account with a banker is incomparably more general, in Scotland than in England. In 1847 it was estimated that the total of deposits in the Scotch banks was not less than 30,000,000*l.*; in 1858, several witnesses before the Committee on Banking spoke of the probable amount as not less than 50,000,000*l.* Of late years there has been a great increase in the number of branch banks (no new banks have been erected since 1845); and the aggregate of the banks, including branches, is larger than the aggregate of banks and branches in England. To a considerable extent there prevails a desire amongst Scotch bankers that the Bank of England note should be made a legal tender in Scotland. ('Evid. before Committee,' &c. 1858. Q. 3197-3199.)

(The works consulted in the preparation of the foregoing article were the following: Smith's *Dict. of Greek and Roman Antiquities*; Adam's *Roman Antiquities*; Gilbart's *Logic of Banking*; Porter's *Progress of the Nation*; Lawson's *History of Banking*; *The Bankers' Magazine*; *The Evidence before the Committee on Bank of England Charter Acts, &c.*, 1858; and others.)

BANK NOTE MANUFACTURE. Considerable mechanical ingenuity has been shown in devising the best modes of manufacturing bank notes, to ensure that they shall be light, durable, and not easily imitated by forgers. The making of the paper, the engraving of the steel-plate, and the numbering of the notes, have all called forth this ingenuity.

Many of the banks in the United States have adopted the use of a peculiar kind of paper made expressly for bank notes. There are introduced into the body of the piece of paper for each note as many cotton threads as will show the value of the note in dollars, up to certain limits: or at least, that a definite number of threads shall represent a definite value in the note; so that no chemical or mechanical tampering with the printed part of the note will prevent the paper from revealing the true original value.

In respect to the plates from which bank notes are printed, they used formerly to be formed of copper; but as this material soon wears away, a mode of using steel plates was devised by Messrs. Perkins and Heath, by which a surprising number of copies may be taken. A block or thick plate of steel is softened on the upper side; the device is engraved on this softened surface; the block is hardened by a very careful process after the engraving; the device is transferred, by intense pressure, from the hardened block to the convex surface of a small soft steel roller; the roller is hardened, and the device is transferred from it to any number of softened steel plates; and lastly, these plates are hardened after the transfer, and are then in a state to be printed from. By this beautiful train of operations one originally engraved block is made to suffice for an almost endless number of printings.

The mode in which the writing, the emblems, and the ornaments are combined in a bank note, is so planned as to render forgery difficult. The *numbering* is a remarkable process, as now performed. In 1809, the Bank of England adopted a numbering press invented by Mr. Bramah, by which the expense and uncertainty of finishing annually a large number of bank notes with a pen were materially diminished, and forgery rendered more difficult. The machine was, however, so far incomplete that it produced only units, the tens and hundreds requiring to be brought forward by hand. In 1813 a machine invented by Mr. John Oldham, and used at the Bank of Ireland, had the additional power of effecting numerical progression, from 1 to 100,000, by its own operation; one of these machines was subsequently attached to each press for printing the body of the notes, in order to register and check the number of notes passing through the press.

In 1819 Mr. Bryan Donkin invented a counting machine, applicable to the numbering of notes. Like most others of the kind, its action depended on the relative motions of a series of ratchet wheels with projecting rims, having notches cut in them; so that when the first wheel counted units, the second wheel indicated tens, and so on progressively. When Mr. Thomas Oldham succeeded his father, Mr. John Oldham, as engineer to the Bank of England, he endeavoured to improve on the instruments previously constructed, and devised the following form of apparatus:—Four wheels each divided by ten notches, leaving a facet between each pair, engraved with consecutive numbers from 1 to 0, are placed upon a shaft; a portion of their breadth being turned down about one-half of their depth, having a boss or collar between every two. Upon these bosses, and filling up the spaces, rest latches; and over each wheel is a pall, the width of the first being equal to that of the unit wheel, and the breadth of the others equalling that of the wheel and latch. The palls are driven by a crank; by each revolution of which the first wheel is moved through a space equal to one-tenth of its entire circumference, bringing regularly forward the numbers from 1 to 0. When the figure 0 is reached, the latch of the second wheel is depressed, and the wheel moves forward one division, marking the tens. The same process is repeated with regard to the other wheels; and thus any amount of numbers can be registered, by simply increasing the number of wheels in proportion. Machines of this kind were extensively adopted in the Bank of England; with, of course, an inking apparatus to apply to the types.

A patent was taken out in 1844 for a mode of printing bank notes, intended to obviate the liability to forgery. The surface is covered with two designs, one geometrically regular, and the other very irregular; the two designs are engraved on different plates, and are printed with different inks, the one with visible and the other with invisible ink. Both of the inks are delible or removeable by chemical means; and the usual engraving of a bank note is printed on paper which has already undergone this preparatory or ornamental printing. The rationale of the suggestion is this: that whatever means a forger might take to alter by chemical agency the letters or figures, or to transfer them by lithographic or anastatic processes, the state of the paper would betray him; for he would remove some parts of the design in the one case, and fail to transfer it in the other. The method was patented on individual responsibility, and has not been adopted by the Bank of England.

Notwithstanding all the ingenuity displayed, and novelties introduced, the commercial world has never felt satisfied as to the security of bank notes from forgery. Public bodies have more than once taken up this subject. In 1819 the Society of Arts appointed a committee to inquire into the best modes of engraving and printing bank notes; and many persons are now of opinion that if the report of that committee had been acted on, the forgeries during the last forty years would have been less numerous than they have been. The enquiries were suggested, not merely by the commercial loss consequent on forgeries, but by a repugnance on the part of the public to the terrible punishment inflicted for this crime. Between the years 1797 and 1817, there were 870 prosecutions for forgery of bank notes, followed by the execution of more than 300 persons. In six years, 1812 to 1818, more than a hundred thousand forged notes were stopped at the Bank; sometimes they poured in at the rate of a hundred a day. Not only did the Society of Arts take up the subject, but a Government Committee was also appointed, to which no fewer than 180 projects (mostly relating to intricate designs of note-engraving) were submitted. It is remarkable, however, how little practical benefit resulted from all these enquiries; the suggested inventions were neglected, and almost went out of recollection. Down to the year 1855, all the bank notes were produced by various combinations of the inventions of Perkins and Heath, Bramah, Oldham, and Donkin, already adverted to. The paper was made at one particular paper-mill in Hampshire, by a peculiar and special operation. [PAPER MANUFACTURE.] The engraving was effected by the transfer method above described, sometimes called *siderographic;* the engraving being transferred and re-transferred, from dies to rollers, and from rollers to plates, having various degrees of hardness. The engraving of two notes was upon one plate. The sheets of paper (each for two notes) were damped for printing, by the operation of an ingenious exhausting vessel, which forced moisture into them at the rate of 30,000 sheets per minute. In the printing room of the Bank of England, after the plates had been heated over steam-boxes, they were printed with steam power. The printing was of the "copper-plate" kind, unlike surface or "letter-press" printing; that is, the ink went into the cavities of the device on the plate, and not upon the surfaces. By a very delicate piece of mechanism, the printing presses recorded the amount of their own work on a registering dial; so that any surreptitious printing was impossible. The working power was generally such as to print about 30,000 bank notes per day. The ink, like everything else in the operation, was specially prepared; it was made from the charred husks of Rhenish grapes, combined with boiled and burnt linseed oil; and it was the blackest and most indelible of all inks. The prevention and detection of forgery were attempted by the truly remarkable mode invented by the Oldhams for printing something or other on every note different from every other note. These varying elements were *dates, numbers,* and *denominations.* There might be many notes of the same date, many bearing the same number, many of the same denomination; but never any two notes that agreed in all these three particulars. These results were produced, partly by the mechanism of the register-printing machines, and partly by the use of certain secret numbers and symbols, known only to the Bank authorities.

Such, we have said, was the mode of operation down to the year 1855; and such in many of its features is the plan still adopted; but important changes have been made in other particulars. In 1851, Mr. Smee, surgeon to the Bank of England, suggested to the directors that the time had arrived for the adoption of *surface* printing instead of *plate* printing, in the preparation of the notes, as admitting of greater rapidity, and more complete identity of appearance. Although objecting to any additional change in the form or device of the note, the directors consented to the prosecution of a series of elaborate experiments. In these experiments Mr. Smee was assisted by Mr. Hensman, engineer to the Bank, and by Mr. Coe, superintendent of the note-printing machines. Engravers, press-makers, paper-makers, and ink-makers, all contributed their opinions or inventions towards the preparation of bank notes by surface-printing. At length, in 1854, all the difficulties were surmounted: on the 1st of January, 1855, the first bank note appeared under the new system. The bank note differs very little from its predecessor; the Britannia is, perhaps, somewhat more artistic; but the letters, figures, and flourishes are scarcely altered. Indeed, it was a fixed policy on the part of the directors to render any change in the appearance of their bank notes as little perceptible as possible. The great novelty was in the preparation of the plate for surface-printing. Until the year 1837, the device was engraved on the plate itself from which the impressions were to be printed; from 1837 to 1854, the engraving was managed on the siderographic process; but on the new system, introduced in 1855, the design for the note is made up and engraved on several small pieces of copper, brass, and steel, according to the quality and minuteness of the engraving; the lines of the device being raised instead of sunken. From the model thus made a metallic mould is obtained, by electro-deposition. Mr. Smee's platinised silver voltaic batteries are employed as the source of power. These batteries had already been advantageously used in multiplying the copper-plates for the Ordnance maps. The model is left in the precipitating-trough containing sulphate of copper solution until a layer of copper has been deposited upon it thick enough to bear handling; the device of course appears on this film in intaglio, not in relief, and serves as the mould from which copies of the original model are to be made. Being separated from the original model, and again immersed in the solution, this mould receives a deposit, which, when thick enough, is separated from the mould giving the device. It is this, in relief instead of intaglio, when backed up and strengthened by solder or other metal, which forms the plate from which Bank of England notes are printed. There are about seventy or eighty kinds of Bank of England notes, differing either in their denominations (*5l.*, *10l.*, &c.), or in the town where they are issued (London, Manchester, Birmingham, &c.); each of these has required its own original model; but any one model would suffice for an almost endless number of notes,—seeing that one model will yield an indefinite number of moulds, and one mould an indefinite number of plates; by the electro-metallurgic process, nearly ten million bank notes are printed annually without any necessary renewal of the original models. The paper, supplied by the same establishment in Hampshire which has furnished bank note paper for a long series of years, is manufactured in a manner which exhibits almost as many novelties as the preparation of the plates. Until the year 1855, the 'water-mark' (one of the safeguards against forgery) was produced by forming a device with fine wire in the mould or frame employed in making the paper. Now, however, the device for the water-mark is engraved on steel-faced dies, and transferred by stamping to brass plates; by a delicate process, these brass plates are adjusted to or within the paper-making mould. There is a gradation of light and shade in the present water-mark, very difficult to imitate. The sheets of paper, before they leave the Hampshire mill, undergo a process of dry-glazing by rolling. It has been necessary to make a change in the ink as well as in the paper, in adapting the arrangements for surface-printing; the bank note ink, instead of being prepared from the husks of Rhenish grapes, is made by a combination of a peculiar varnish with the soot resulting from burning coal-tar naphtha in closed chambers. The printing presses, and the mode of printing, differ materially under the present surface-printing system, as compared with the old plate-printing; the mechanism comprises many beautiful novelties.

Excellent as are now the Bank of England notes, there are not wanting experienced men who contend that a more elaborate device, practicable only by the plate-printing method, would be better. Forgery has diminished, but it has not quite died out. The Bank directors opposed any marked change in the simplicity of the device on these grounds:—that forgers can imitate elaborate engraving sufficiently well to deceive the public, if not bank clerks; that parti-coloured notes, invented by Sir William Congreve, were successfully imitated; that the general public, not being judges of artistic effect, and having little discrimination for the different styles of different artists, are apt to be easily deceived by the same *general* appearance in a forged note that they have been familiar with in a real note, and take imperfect imitations of it quite as readily; and that, on the whole, long familiarity with one form of inscription, and one style of ornament, is the best preventive against forgery. These opinions were contested by Mr. Henry Bradbury, in a Lecture delivered at the Royal Institution, on the 9th of May, 1856; the lecture was afterwards printed as a quarto pamphlet, with engravings of three specimen bank notes, from designs by Mr. John Leighton. Mr. Bradbury contends that the object to be aimed at should be to impart to each bank note an individuality, thereby expressing qualities which are not within the province of mechanical imitation. This is to be done by employing a design of a high artistic character; seeing that the work which has the genius of an artist imprinted on it, is not to be imitated by an inferior mind. The vignette is the part of a note on which the most artistic skill is displayed; and Mr. Bradbury urges that this skill should be still further exercised. Early in the present century the Plymouth Dock Bank, to lessen the forgery of its notes, caused a vignette to be engraved; the forgeries at once ceased. When a really skilful artist can engrave a vignette of high character, his social position and prospects are such as to take him out of the influence and temptation of forgers. The higher the class of the engraving, the less the likelihood of forgery; seeing that the work of every real artist has an individuality about it which others could not imitate. Admitting that the Bank of England note exhibits simplicity of design, Mr. Bradbury remarks, "The objection I have to submit is that its simplicity is *too* simple,—not having upon the face of it those features which characterise the true art-point. The vignette is a specimen the reverse of what I have been advocating; it is alike deficient in conception and execution. Surface-printing having been chosen as the medium, the Bank authorities were restricted in the application of their art. In consequence of this, the Bank of England note in its present form is unworthy of the bank and the nation." Assuming that high art should be employed to give character to the simplest parts of the note, Mr. Bradbury would employ machine-engraving—such as medallion work, and guilloche or rose-engine work—to produce ornamental details of any desired degree of complexity; straight lines, waved lines, circles, ellipses, &c., may be combined in ways almost illimitable. To produce these results—the combination of high art, simplicity with mechanical intricacy, as a double check to the forger—Mr. Bradbury believes that plate-printing would be necessary. Mr. Grubb, engineer to the Bank of Ireland, has expressed opinions very similar to those of Mr. Bradbury.

The electrotype is resorted to as the most perfect and practical mode for multiplying the number of plates. The objection formerly raised to the use of copper is entirely removed; if a copper-plate be covered by electro-deposition with a thin coating of iron or zinc, an unlimited number of impressions may be printed from it: and as the coating can be removed and renewed at pleasure, and *ad libitum*, without the slightest injury to the plate, copper-plates by this treatment will entirely supersede the use of steel-plate engraving and siderography for bank notes.

It may be remarked, that while the current coin of the realm is made at the Government Mint on Tower Hill, the Bank of England notes, which are the property of that corporation, and not of the state, are prepared within the walls of the Bank in Threadneedle Street.

BANKRUPT (*banque-routier*, a bankrupt, and *banque-route*, bankruptcy—from *bancus*, the table or counter of a tradesman, and *ruptus*, broken) is a merchant or trader whose property and effects, on his becoming insolvent, are administered and distributed for the benefit of all his creditors, under that peculiar system of statutory regulations called the Bankrupt Laws. These laws, which originated in England with the statute 34 & 35 Henry VIII. c. 4, were first mainly directed against the criminal frauds of traders, who acquired the merchandise and goods of others, and then fled to foreign countries, or lived in extravagance, and eluded and defrauded their creditors. The bankrupt was consequently treated as a criminal offender; and formerly, the not duly surrendering his property under a commission of bankruptcy, when summoned, was a capital felony. The bankrupt laws are now, and have for some time past, been regarded as a connected system of civil legislation, having the double object of enforcing a complete discovery and equitable distribution of the property and effects of an insolvent trader, and of conferring on the trader the reciprocal advantage of security of person and a discharge from all claims of his creditors. These laws were till lately spread over a voluminous accumulation of statutes, referring to and depending on each other, and often creating confusion and inconvenience from their diffuse and contradictory provisions. These were, under the auspices of Lord Eldon, repealed, and their provisions altered and consolidated by the general Bankrupt Act (6 Geo. IV. c. 16), which also introduced many important alterations and simplifications. A subsequent statute, 1 & 2 Will. IV. c. 56, constituted 'the Court of Bankruptcy,' and materially altered the mode of administration of this law: it entirely removed the jurisdiction in the first instance in cases of bankruptcy from the Court of Chancery to a Court of Bankruptcy, reserving only an appeal from the judges of that court to the Lord Chancellor, as to matters of law and equity and questions of evidence. Instead of the commission under the Great Seal, which formerly issued to a certain number of barristers-at-law who were permanent Commissioners of Bankruptcy, the above Act substituted a *fiat* of bankruptcy, and introduced other important alterations. This statute was followed by the 5 & 6 Will. IV. c. 29, which reduced the number of judges of the Court of Review, established by the previous act, from four to three; and by the 5 & 6 Vict. c. 122, which introduced some alterations into the law of bankruptcy, further modified the constitution of the Court of Review, and established country courts of bankruptcy in the place of the local commissioners of bankrupt, to whom fiats in bankruptcy were previously directed.

The numerous statutes relating to bankruptcy have again been consolidated by the Bankrupt Law Consolidation Act, 1849, and this has been amended in a few particulars by the 15 & 16 Vict. c. 77, and by the Bankruptcy Act, 1854. These three acts embody the actual law applicable directly to bankrupts and to their estates.

In considering the provisions of the Bankrupt Law, we must explain—

1. Who may be made a bankrupt.
2. By what acts a trader becomes liable to be made a bankrupt.
3. The proceedings by which a trader is made a bankrupt.
4. The assignees, their powers and duties; and the vesting of the bankrupt's property and effects in them.
5. The examination and certificate of the bankrupt.
6. The proof of debts by the creditors.
7. The effect of the bankruptcy on the rights of third parties.
8. Arrangements between bankrupts and their creditors under the control of the court, or by deed; and composition of bankruptcy.
9. The constitution of the Court of Bankruptcy.

1. *Who may be made a Bankrupt.*—The Bankrupt Law Consolidation Act, 1849, s. 65, enacts, that "all alum makers, apothecaries, auctioneers, bankers, bleachers, brokers, brickmakers, builders, callenderers, carpenters, carriers, cattle or sheep salesmen, coach proprietors, cow-keepers, dyers, fullers, keepers of inns, taverns, hotels, or coffee-houses, lime-burners, livery-stable keepers, market gardeners, millers, packers, printers, ship-owners, shipwrights, victuallers, warehousemen, wharfingers, persons using the trade or profession of a scrivener receiving other men's moneys or estates into their trust or custody, persons insuring ships or their freight or other matters against the perils of the sea, and all persons using the trade of merchandise by way of bargaining, exchange, bartering, commission, consignment, or otherwise, in gross or by retail, and all persons who, either for themselves or as agents or factors for others, seek their living by buying and selling, or by buying and letting for hire, or by the workmanship of goods or commodities, shall be deemed traders liable to become bankrupt; provided that no farmer, grazier, common labourer, or workman for hire, receiver-general of the taxes, or member of or subscriber to any incorporated commercial or trading company, established by charter or act of Parliament, shall be deemed as such a trader liable to become bankrupt."

The above enumeration has given rise to a variety of decisions in the courts of law. It is not every single act, or even every series of acts, of buying and selling which constitutes a man a trader within the law: there must be an intention of dealing generally, and of gaining a livelihood by trading. Thus a schoolmaster who sells books to his scholars; a colonel of militia, who occasionally sells regimental horses; a master of hounds, who buys dead horses, and sells off the skin and bones; a farmer who sells the milk of his cows to a retail dealer, or who buys and sells articles not with a view of making profit, but merely as auxiliary to the carrying on his farm;—these and many similar persons have been held not within the bankrupt laws as traders. And the same has been determined with respect to an owner of coal-mines, who digs and sells his coals; a person having a freehold interest or a term of years in a brick-ground, who sells the bricks made from his brick-earth, though if he purchased the materials for making bricks it would be otherwise. If a trader retires from trade, still while his trading debts remain unpaid he may be made a bankrupt in respect of them, but not in respect of debts contracted after his retirement.

2. *The acts by which a Trader becomes liable to be made a Bankrupt.*—These acts are of two sorts: first, those which are only acts of bankruptcy when done with *intent* to defeat or delay his creditors; secondly, certain acts which have that effect, without reference to any intention. The first class are enumerated in section 67 of the Bankrupt Law Consolidation Act, 1849, which enacts, "that if any trader liable to become bankrupt shall depart this realm, or being out of this realm shall remain abroad, or shall depart from his dwelling-house, or otherwise absent himself, or begin to keep his house, or suffer himself to be arrested or taken in execution for any debt not due, or yield himself to prison, or suffer himself to be outlawed, or procure himself to be arrested or taken in execution, or his goods, money, or chattels to be

attached, sequestered, or taken in execution, or make or cause to be made either within this realm or elsewhere any fraudulent grant or conveyance of any of his lands, tenements, goods, or chattels, or make or cause to be made any fraudulent surrender of any of his copyhold lands or tenements, or make or cause to be made any fraudulent gift, delivery, or transfer of any of his goods or chattels; every such trader doing, suffering, procuring, executing, permitting, making, or causing to be made, any of the acts, deeds, or matters aforesaid, with intent to defeat or delay his creditors, shall be deemed to have thereby committed an act of bankruptcy." A few observations will elucidate the several acts of bankruptcy mentioned in the above clause.

Departing the realm.—This must be done with a view to defeat or delay creditors, or it will not constitute an act of bankruptcy; but if it is done with such intention it is an act of bankruptcy, though no creditor may, *in fact*, be delayed by it. The intention is, in general, a question of fact to be decided by a jury. If a man leave the realm in such circumstances that a delay of his creditors will be the almost necessary consequence of his departure, he will be considered to have intended that they should be delayed within the meaning of the law. The word *realm* means the jurisdiction of the courts of England, and therefore departing to Ireland or Scotland, or a British colony, which are out of such jurisdiction, may constitute an act of bankruptcy.

Trader departing from his dwelling house.—If this is done with the intent to delay creditors, it is an act of bankruptcy, though none are actually delayed. And if the trader departs without making the necessary arrangements for carrying on his business, it will be presumed that he had the intention specified in the act. The absence must be voluntary, in order to constitute an act of bankruptcy. And the trader's own declarations of his bad circumstances, of his fears of arrest, &c., are evidence of his intentions, if they accompany corresponding *acts*, such as removing his goods, books, &c.

Or otherwise absent himself.—A trader's absenting himself from his abode, if voluntarily done, and not by means of an arrest, is primâ facie evidence of his intention to delay his creditors. And the absenting himself from the Royal Exchange, if he habitually frequents it, or from any temporary place of resort, may have the same effect. The proprietor of a theatre retiring behind the scenes and giving orders to be denied, was held to commit an act of bankruptcy. But a mere breach of an appointment with an individual creditor will not be so considered, though the breach of an appointment to meet creditors generally may be an act of bankruptcy.

Or begin to keep house.—These words having been adopted in the early statutes respecting bankrupts, have acquired a well-known technical meaning, signifying the trader's retiring or concealing himself in his house or place of business in order to avoid creditors, or the giving orders to be denied in case they should call. A general order of denial is not an act of bankruptcy, unless followed up by actual denial, or by some other act which is evidence of a beginning to keep house. The denial may be at a friend's house, as well as at the house of the trader himself. Closing the doors and shutters of a banking-house has been held a "beginning to keep house," although the trader did not reside at the banking-house.

Or suffer himself to be arrested or taken in execution for any debt not due, or yield himself to prison.—This must be a voluntary yielding to prison by a trader who either is not bonâ fide indebted to the person on whose behalf he is arrested, or who, on his arrest, has funds to pay the debt, but prefers going to prison with a view to defeat his general creditors. A compulsory going to prison under a bonâ fide arrest is only an act of bankruptcy when the imprisonment endures twenty-one days.

Or suffer himself to be outlawed.—That is, if a man keep out of the way with intent to defraud his creditors, in consequence of which he is outlawed for want of due appearance to legal process.

Or fraudulently procure his goods to be attached, &c.—This extends both to fraudulent attachments of the trader's goods under the custom of foreign attachment in London and other cities [ATTACHMENT], and to fraudulent judgments, executions, and attachments (Common Law Procedure Act, 1854), out of the superior courts.

Or make, either within the realm or elsewhere, any fraudulent grant or conveyance of his lands, tenements, goods or chattels.—A conveyance of the trader's property, if executed abroad, is now held an act of bankruptcy.

An assignment of *all* a trader's effects to trustees for the benefit of creditors is a clear act of bankruptcy, since it deprives him of the power of carrying on his trade, goes to defeat the distribution under the Bankrupt Law, and to vest the property in persons of his own choice, instead of those provided by the law. But if *all* the creditors (as often happens) assent to, and sign such an instrument, it becomes valid, since they are then *estopped*, by their assent, from treating it as an act of bankruptcy. And by the 68th section of the Bankrupt Law Consolidation Act, 1849, such an assignment is not to be deemed an act of bankruptcy, unless a petition for adjudication be filed against the trader within three calendar months from the execution; provided the assignment be executed by every trustee within fifteen days from the date of the execution by the trader, and the execution be attested and publicly notified in the manner pointed out by the statute.

An assignment of *part* of a trader's effects is, in many instances, perfectly good and valid; but if he assign the whole with only some colourable exception, it is an act of bankruptcy; and, in general, if he assign over so considerable a proportion of his stock-in-trade and effects as must disable him from carrying on his trade, it is an act of bankruptcy; and if the assignment be made voluntarily, that is without the pressure of the creditor, and with a view to prefer a particular creditor, or creditors, it will, though not made in immediate contemplation of bankruptcy, constitute in itself an act of bankruptcy; and, *à fortiori*, it will have that effect if made under such circumstances as show that the trader must, at the time of executing it, have contemplated bankruptcy. A bonâ fide sale, even if under value, is clearly not an act of bankruptcy.

Or make any fraudulent gift, delivery, or transfer of any of his goods or chattels.—The transfer or delivery must in general, be *voluntary*, and not brought about by terror of legal process, or even by the importunity of a creditor; and, in some cases, even the circumstance of the proposal to make the delivery coming from the creditor and not from the bankrupt, has been held to negative the inference of voluntariness, and to render the transaction valid. But whether of his voluntary motion, or under pressure of a creditor, if a trader transfer over, otherwise than by bonâ fide sale, the whole of his effects, or such a portion of them as must necessarily lead to insolvency and the stoppage of his trade, it now constitutes an act of bankruptcy.

The acts of bankruptcy above enumerated depend upon the trader's presumable intention in doing the act. The following are the acts which constitute acts of bankruptcy, whether done with or without an intention to delay or defraud creditors.

Lying in prison or escaping out of prison.—By the 69th section of the Bankrupt Law Consolidation Act, 1849, "if any such trader, having been arrested or committed to prison for debt, or on any attachment for non-payment of money, shall upon such or any other arrest or commitment for debt, or non-payment of money, or upon any detention for debt, lie in prison for twenty-one days, or having been arrested or committed to prison for any other cause, shall lie in prison for twenty-one days after any detainer for debt lodged against him and not discharged, every such trader shall thereby be deemed to have committed an act of bankruptcy; or if any such trader having been arrested, committed, or detained for debt, shall escape out of prison or custody, every such trader shall be deemed to have thereby committed an act of bankruptcy from the time of such arrest, commitment, or detention."

The bankrupt law does not now, and never did, make the mere circumstance of being arrested an act of bankruptcy. The most substantial trader is liable, under unforeseen emergencies, to be arrested; the presumption of insolvency arises from the fact of lying in prison twenty-one days without being able to satisfy the debt, or of escaping out of prison to avoid its payment.

Filing a declaration of insolvency.—Under the old law no effectual provision was made for enabling an honest debtor, who believed himself insolvent, voluntarily to subject himself to the bankrupt law, and thereby to produce an equal distribution of his property among his creditors. It is now provided that if a trader file, in the court within the district whereof he shall have resided or carried on business for the preceding six months, a declaration of his insolvency, signed by himself, and attested by an attorney, such trader shall be deemed thereby to have committed an act of bankruptcy at the time of filing such declaration, provided a petition for adjudication of bankruptcy shall be filed by or against such trader within three months from the filing of such declaration.

Compounding with petitioning creditor.—By the 71st section of the Bankrupt Law Consolidation Act, 1849, it is provided that if any trader, after the filing of any petition for adjudication against him, shall pay money to the petitioning creditor, or give or deliver to such petitioning creditor any satisfaction or security for his debt, or for any part thereof, whereby such petitioning creditor may receive more in the pound in respect of his debt than the other creditors, such payment, gift, delivery, satisfaction or security shall be an act of bankruptcy; and if adjudication of bankruptcy shall have been made under such petition, the court may either declare such adjudication to be valid, and direct the same to be proceeded in, or may order it to be annulled, and a petition or new petition for adjudication may be filed, and such petition or new petition may be supported either by proof of such last-mentioned, or any other act of bankruptcy.

Trader not paying, securing, or compounding for a judgment debt within seven days after notice requiring payment.—By the Bankrupt Law Consolidation Act, 1849, s. 72, it is provided that if a trader, against whom a judgment has been recovered in an action personal for the recovery of a debt or money demand, shall, after seven days notice in writing, personally served upon him, requiring immediate payment of such judgment debt, fail to pay, secure, or compound for the same, he shall be deemed to have committed an act of bankruptcy upon the eighth day after service of such notice. To give or proceed upon such a notice the judgment creditor must be in a condition to issue execution upon his judgment.

Trader disobeying order of Court of Equity, &c.—By the Bankrupt Law Consolidation Act, 1849, sec. 73, it is provided that if a trader disobey any decree or order for the payment of money made by a court of equity, or in any matter of bankruptcy or lunacy, and duly served upon him, the court by which such decree or order was made may, by its further order, fix a peremptory day for such payment, and if such trader having been personally served with such last-mentioned order seven days before such peremptory day, fail to pay the money as ordered, he shall be deemed to have committed an act of bankruptcy on the eighth day after service of the order.

Filing petition in Insolvent Debtors' Court in England.—By the Bankrupt Law Consolidation Act, s. 74, it is provided that the filing by any trader of a petition in the Court for the Relief of Insolvent Debtors, for discharge from custody, shall be deemed an act of bankruptcy, from the time of filing such petition, if such trader be adjudicated a bankrupt before the time appointed for his being brought up to be dealt with according to the laws for relief of insolvent debtors, or within two months from the making of any vesting order by such insolvent court. The property of such trader by such subsequent adjudication becomes divested out of the provisional assignee of the Insolvent Court.

Insolvency in India.—Analogous provision to the above is made by s. 75, for the case of traders filing petitions in India under the "Act to consolidate and amend the Laws relating to Insolvent Debtors in India."

Arrangement between trader debtor and his creditors.—Section 76 of the Bankrupt Law Consolidation Act, 1849, provides that filing a petition for arrangement by a trader under a subsequent section (211), shall constitute an act of bankruptcy if a petition for adjudication be filed against him within two months from the dismissal of such petition for arrangement.

Acts of bankruptcy by traders who have privilege of Parliament.—As traders being members of parliament are not liable to personal arrest for debt during the time of privilege, some special provisions are requisite as to acts of bankruptcy committed by such persons. Accordingly, it is provided by the Bankrupt Law Consolidation Act, 1849, s. 77, that if any creditor of such trader in an amount sufficient to support an adjudication of bankruptcy, shall file an affidavit of such debt and of the trading in one of the superior courts, and shall sue out of the same court a writ of summons in the special form provided by the Act, and personally serve the same; and if such trader shall not within one month after such service, pay, secure, or compound, for such debt; or give sufficient security for debt and costs in the action, and within the month cause an appearance to be entered in the action, such trader shall be deemed to have committed an act of bankruptcy from the time of the service of the summons.

Non-payment of debt after trader debtor summons.—The Bankrupt Law Consolidation Act, 1849, lastly provides, s. 78, et seq., that a trader upon whom an account of the particulars of a creditor's demand, together with a notice in writing in the form provided by the Act, requiring immediate payment has been served in the manner also by the Act provided, may, upon formal affidavit filed in the Court of Bankruptcy for the district in which the trader resides, and upon summons issued out of such court, be required to appear in such court, and to state whether he admits the debt or not. If he admits it, he is required to sign a formal admission, to be filed in the court, and if he fails to pay the sum admitted within seven days after filing the admission, he is deemed to have committed an act of bankruptcy on the eighth day from the filing the admission. But if he fails to appear or refuse to admit the debt, and do not make a formal deposition upon oath that he believes he has a good defence upon the merits, and do not, if required by the court, enter into a bond with sureties, as provided by the Act, he is deemed to have committed an act of bankruptcy upon the eighth day after service of the summons to appear. But in either case the petition for adjudication must be filed within two months from the filing of the affidavit.

This process by trader debtor summons, as it is called, is found very effective for the recovery of debts, and is much resorted to for that purpose notwithstanding the penalty imposed upon exaggerated claims by s. 86, and the discretion as to costs vested in the court by s. 85. The advantages presented to creditors are expedition and economy in recovering the debt if admitted by a solvent trader, while if denied the trader is put to his affidavit, and may be required to find security for the debt and for the creditor's costs of suit. Traders who are really indebted are thus compelled either to pay their debts summarily or to submit to an otherwise immediate bankruptcy. Great care, however, should be taken in employing this process, and if collateral with an action it should rarely be resorted to until after the defendant has pleaded.

The above are the various and the only acts which, according to the present law, render a trader liable to an adjudication of bankruptcy. No other acts, however strongly they may indicate insolvency or fraudulent intention in the trader, are sufficient to render him a *bankrupt*. The act of bankruptcy may be committed after a trader has ceased trading; for so long as his *trading* debts remain unpaid, he is amenable to the law of bankruptcy. The debt, however, on which the adjudication is grounded must, as before stated, be one which existed during the period of his trading. An act of bankruptcy, in order to support an adjudication, must have been committed within twelve months before filing the petition.

3. *Of the proceedings by which a Trader is made a Bankrupt*—Having considered what persons may be rendered bankrupts, and the several acts and circumstances by which they may become so, we will now shortly explain the peculiar mode of proceeding by which creditors render their debtor a bankrupt.

The adjudication of bankruptcy is made upon a petition of one or more creditors to the Court of Bankruptcy.

If on the single petition of one creditor, his debt must amount to 50*l.*; if of two creditors, not being partners, to 70*l.*; if of three or more such creditors, to 100*l.* This debt must have been contracted while the bankrupt was in trade, or must at least have been at that time subsisting; and it must have been actually due at the time of the act of bankruptcy. If the debt of the petitioning creditor appears on any ground insufficient, the adjudication may be supported on any other debt of another creditor which is legally adequate to sustain it, sec. 103. The petitioner files and prosecutes his petition at his own costs until the choice of assignees by the creditors, and is entitled to have them paid back to him out of the estate when realised. See 'Bankrupt Law Consolidation Act,' 1849, s. 114, and 'Rules and Orders in Bankruptcy,' 114 & 115. If it appear that the debt alleged in the affidavit is not due to the petitioning creditor, or no proof be given that the person petitioned against is or was a trader, and that he committed an act of bankruptcy, and that the petition was filed fraudulently and maliciously, the court may order satisfaction to be made. If the petitioning creditor compound with the bankrupt after adjudication, so as to receive more in the pound than the other creditors, he is liable to forfeit his whole debt, and to repay and deliver up all money or securities received, to the assignees for the benefit of the creditors. In the case of a firm of traders, any creditor whose debt is of sufficient amount may petition either against the firm collectively, or against one or more partners in it. The petition must, unless otherwise specially ordered, be addressed to, and filed, and prosecuted in the court for the district within which the trader shall have resided or carried on his business for six months next preceding the filing the petition. The form of petition is provided by the statute, and its truth must be verified by the affidavit of the petitioner. Upon proof of the petitioning creditor's debt, of the trading, and of the act of bankruptcy, the court adjudges the trader a bankrupt. A trader may petition for an adjudication of his own bankruptcy, and upon his application and proof of his trading, and of the filing and declaration of insolvency, and of his available estate being sufficient to produce at least 150*l.*, the court similarly adjudges him a bankrupt. Immediately after adjudication, an official assignee is appointed by the court, whose duty it is at once to take possession of all the bankrupt's property.

Notice of the adjudication is given to the bankrupt, that he may, if so advised, show cause against it; this he is at liberty to do within seven days, giving two days' notice in writing thereof, and of the grounds of objection to the petitioning creditor or his solicitor, and to the registrar of the court. The necessary proofs must be again given, and the adjudication is thereupon either annulled or sustained. There is an appeal from the Commissioner to the Lords Justices of Appeal in Chancery, and from their judgment to the House of Lords. If the adjudication is submitted to, or sustained, the commissioner causes notice thereof to be given in the 'London Gazette,' and at the same time appoints two public sittings of the court for the bankrupt to surrender and conform, and for the election of creditors' assignees. This advertisement becomes conclusive evidence as against the bankrupt of the date of the petition being filed, and of his bankruptcy before such date, unless he shall within two calendar months thereafter (if within the United Kingdom, and if elsewhere, within an extended period), have commenced, and shall duly prosecute an action or other proceeding to dispute or annul the adjudication. The bankrupt is at liberty, however, to surrender at any time before the time limited, by appearing in court and signing a memorandum to that effect, on which he obtains an order of protection from arrest at the suit of any creditor, until the next sitting of the court.

4. *The Assignees, their powers and duties, and the vesting of the Bankrupt's property and effects in them.*—At the first of these sittings an election must be made of assignees, or persons to whom the bankrupt's estate shall be assigned, and in whom it shall be vested for the benefit of the creditors; which assignees are to be chosen by the major part in value of the creditors who shall then have proved their debts; but no creditor shall be admitted to vote in the choice of assignees, whose debt, on the balance of accounts, does not amount to 10*l.*

In the mean time, however, and immediately on the adjudication being made, the official assignee becomes the depository of all the bankrupt's property, and if the court so order, he may, before the creditor's assignees are chosen, sell or dispose of goods of a perishable nature, or other property, the holding of which until the choice of assignees would prejudice the bankrupt's estate. The official assignee receives all rents, interest, proceeds of sale, or other monies which may accrue from the bankrupt's estate, and places them in the Bank of England. All books, papers, and accounts relating to the estate must be delivered up to him, on oath, if required, and the bankrupt must attend him at all reasonable times, to assist in getting in and protecting the estate, for which attendance he is paid at the rate of five shillings a day. The election of creditors' assignees being made, and the selection being ratified by the court, such appointment has the effect of vesting in these assignees, conjointly with the official assignee, all the bankrupt's estate and effects, to be by them held for the benefit of the creditors at large.

By the Act for the Abolition of Fines and Recoveries, 3 & 4 Wm. IV. c. 74, the Court of Bankruptcy may dispose for a valuable consideration of all lands of which the bankrupt is tenant in tail, and thereby create as large an estate as the bankrupt himself might have done had he not become bankrupt. The copyhold estate of the bankrupt does not pass to the assignees by virtue of their mere appointment, but the court is authorised to convey such property to any person who purchases it. The purchaser is to agree and compound with the lord of the manor wherein it is situate for the fines and services, and the lord shall at the next court grant the property to the vendee. Contingent estates and interests in real property which belong to the bankrupt pass to the assignees; but the expectancy of an heir-at-law (or possibility, as it is technically called) is not such an interest as vests in the assignees. Offices of an inheritable nature, or such as are held for a term of years, are in general saleable, and therefore pass to the assignees, provided they do not concern the administration of public justice; and as an officer on half-pay cannot sell his half-pay, so on principles of public policy, he cannot be called on to discover or surrender it in case of his becoming a bankrupt. All the debts and choses in action due to the bankrupt vest in his assignees, who have a right to sue upon all beneficial contracts entered into with the bankrupt before his bankruptcy, and also for all torts and injuries affecting his *property;* but not for mere personal wrongs, such as assaults, slanders, libels, and the like. The right to bring a real action passes to the assignees, even though the estate may be the bankrupt's in right of his wife. The bankrupt's interest in a patent, and his right to publish a newspaper, constitute property which vests in his assignees. As the right of the bankrupt to sue at law on contracts passes to his assignees, so also does his right of suing in equity to enforce their specific performance; but in order to protect vendors who have agreed to sell real property to a trader who becomes bankrupt, the assignees are compelled (on being required) to execute the agreement or to abandon it, or if they fail to do so, the vendor may apply to the Court of Bankruptcy, and the court will order the assignees to deliver up the agreement, or make such other order as it shall think fit. The bankrupt's personal property situated in a foreign country will pass to the assignees, unless the law of the foreign country prevent it. With respect to leases, the assignees are not bound to accept a leasehold interest belonging to the bankrupt unless they think proper; for in some cases such a property is burdened with rent and covenants beyond its value, and would prove a loss to the creditors. Such property, therefore, remains vested in the bankrupt till the assignees have done some act amounting to an acceptance, such as taking possession of it, or intermeddling with it in the capacity of owner; but a mere experiment, by putting it up to sale to ascertain its value, will not constitute an acceptance of it. If the assignees accept the lease, they become liable to the landlord for the rent and covenants, and the bankrupt is discharged from both from the date of the filing of the petition for adjudication. If the assignees decline the lease, the bankrupt is also discharged by the Bankrupt Acts from the rent and covenants, provided he deliver up the lease to the landlord within fourteen days from his having notice that the assignees have declined it; and if the assignees, on being required, fail to elect whether they will accept or decline the lease, the landlord may apply to the Court of Bankruptcy, and the court will order them so to elect, and to deliver up the lease in case they decline it. Property which the bankrupt holds as trustee for others does not pass to his assignees, being in no way beneficial to his creditors. If the bankrupt has stock standing in his name, the court may order it to be transferred into the names of the assignees. Whatever beneficial interest the bankrupt may have in property of his wife passes to his assignees; but property which she enjoys as a *sole trader* in the city of London, or which is settled to her separate use, does not fall within the operation of the bankruptcy. If the assignees are able to recover possession of the wife's property in a court of law, equity will not interfere with their legal title; but if the property is of such a nature that they are compelled to sue in a court of equity to recover it, that court will require a provision to be made for the wife out of the fund. All property which might be redeemed by the bankrupt, may be redeemed by his assignees for the benefit of the creditors. The assignees not only take all the bankrupt's present property, but also property which may accrue to him previously to his obtaining his certificate; but they have no right to seize the profits of his personal and daily labour, for that would be to deprive him of his means of existence. In a case where the bankrupt, a furniture broker, was engaged to remove goods, and he employed, for that purpose, vans, packing-cases, and five or six men, it was held that his demand for this employment passed to his assignees, since it did not consist solely of a remuneration for his personal labour. The right to nominate to a vacant ecclesiastical benefice does not pass to the assignees. To the assignees also pertains the duty of calling meetings, collecting debts, and acting generally for the benefit of the estate under the orders of the court; the official assignee, until assignees are chosen by the creditors, having been, as we have already seen, to all intents and purposes the sole assignee of the bankrupt's estate and effects.

5. *The Examination and Certificate of the Bankrupt.*—At the second of these sittings, at farthest, which must be on a day not less than thirty and not exceeding sixty days from the advertisement in the 'Gazette' (unless the time be enlarged by the court), the bankrupt, upon notice personally served upon him, or left at his usual place of abode, must surrender himself personally to the commissioners; which surrender (if voluntary) protects him from all arrest, unless he has been guilty of certain offences enumerated by the statute, which involve a refusal of protection: and he must thenceforth in all respects conform to the directions of the statutes of bankruptcy; or, in default of either surrender or conformity, shall be guilty of felony, and may be transported for life, or imprisoned for seven years. When the bankrupt appears, the commissioner is to examine him touching all matters relating to his trade and effects. He may also summon before him, and examine, the bankrupt's wife, and any other person supposed to have any of the bankrupt's property in his hands, or to be capable of giving information touching his affairs. And in case any of them shall refuse to answer, or shall not answer fully, to any lawful question, or shall refuse to subscribe such their examination, the commissioner may commit them to prison without bail till they submit themselves, and make and sign a full answer; the commissioner specifying in his warrant of commitment the question so refused to be answered. And any gaoler permitting such person to escape or go out of prison shall forfeit 500*l.* to the creditors.

The bankrupt upon his examination, which may be adjourned from time to time, or *sine die*, is bound upon pain of transportation for life (formerly the penalty was death) to make a full discovery of all his estate and effects, as well in expectancy as in possession, and how he has disposed of the same, together with all books and writings relating thereto: and is to deliver up all in his own power to the commissioners, except the necessary apparel of himself, his wife, and his children; household furniture, tools, and such like necessaries, which, to the amount in value of 20*l.*, are to be allowed to him; and in case he conceals or embezzles any effects to the amount of 10*l.*, or withholds any books or writings, with intent to defraud his creditors, he shall be guilty of felony, and be liable to transportation for life or not less than seven years, or imprisonment for any term not exceeding seven years. Under the rigorous enactment of the statute 21 Jac. I. c. 19, which was not repealed until the year 1816, unless it appeared that his inability to pay his debts arose from some casual loss, he might, upon conviction by indictment of such misconduct and negligence, be set upon the pillory for two hours, and have one of his ears nailed to the same and cut off.

After forty-two days from the filing of the petition have elapsed, any person voluntarily discovering any part of the bankrupt's estate, before unknown to the assignees, is entitled to five per cent. out of the effects so discovered, and such farther reward as the assignees with the consent of the court shall think proper. But any person wilfully concealing the estate of the bankrupt, after the expiration of the two and forty days, shall forfeit 100*l.*, and double the value of the estate concealed.

Hitherto, everything is in favour of the creditors, and the law seems to be pretty rigid and severe against the bankrupt; but, in case he proves honest, it makes him full amends for all this rigour and severity. For, if the bankrupt has made an ingenuous discovery, and has conformed in all points to the directions of the law, the court proceeds to appoint a public sitting for the allowance of the certificate of conformity. And unless there appears cause to the contrary, the court certifies that the bankrupt has made a full discovery, and conformed in all respects. This certificate may in certain cases be suspended for a time, but if the bankrupt be proved to have destroyed or falsified his books or entries, or to have been guilty of any manner of fraud in contracting debts, or to have given a fraudulent preference to any of his creditors, or concealed or made away with any of his property, or given fictitious accounts of his losses and expenses, or put his creditors to unnecessary expense by frivolous defences, or wilfully withheld the production of any book relating to his dealings, or have wilfully omitted to keep proper accounts of his trading, then the court may refuse or suspend the certificate, or annex such conditions to it as the justice of the case may require. And if the bankrupt is shown to have lost 20*l.* in one day by gaming, or 200*l.* within the year next preceding the filing of the petition, or if within the same time he has lost 200*l.* by a time bargain for the purchase or sale of stock, he is not entitled to a certificate, or if he obtains one it is void.

Three classes of certificates are given; the first where the bankruptcy is found to have arisen from unavoidable losses and misfortunes; the second when it has not wholly arisen from such causes; and the third when it has not arisen from such causes at all; and this finding is in every case specified in the certificate. Notice of the allowance of the certificate, the time of suspension (if any), and the conditions of allowance (if any), is given by advertisement in the 'London Gazette,' ten days or more before the time allowed by the statute for appealing against the granting of the certificate; and if no appeal be lodged, the Court at the expiration of the time, on production of the 'Gazette' containing the advertisement, delivers to the bankrupt the certificate of conformity, unless the delivery of the certificate have been suspended. When the certificate has been allowed, the bankrupt is entitled to a decent and reasonable allowance out of his effects, for his future support and maintenance, and to put him in a way of honest industry. This allowance is rendered proportionate to his former good behaviour, in the early discovery of the decline of his affairs, tested by the amount of dividend secured to his creditors. For if his effects will not pay one-half of his debts, or 10*s.* in the pound, he is left to the discretion of the court and assignees, to have a competent sum allowed him, not exceeding three per cent. upon the nett produce of his estate; but if they pay 10*s.* in the pound, he is to be allowed five per cent.; if 12*s.* 6*d.*, then seven-and-a-half per cent.; and if 15*s.* in the pound, then the bankrupt is allowed ten per cent.; provided that such allowance do not in the first case exceed 300*l.*, in the second 400*l.*, in the third 500*l.*, and in the fourth 600*l.* Besides this allowance, he has also an indemnity granted him, of being free and discharged for ever from all debts owing by him at the time he became a bankrupt, and from all claims and demands provable under the bankruptcy, even though judgment shall have been obtained against him, and he lies in prison upon execution for such debts; and for that, among other purposes, all proceedings in bankruptcy are entered of record, as a perpetual bar against actions to be commenced on this account; though, in general, the production of the certificate, properly allowed, is sufficient evidence of all previous proceedings. Thus the bankrupt becomes a clear man again. Thus much for the proceedings in a bankruptcy, so far as they affect the bankrupt personally.

6. *The Proof of Debts by the Creditors, and the effect of Bankruptcy on the rights of third parties.*—Having thus shown the mode in which the trader is declared a bankrupt, and his property and effects are brought under the control of the court for distribution among his creditors, the verification of the creditors' debts is the next step to be considered. The commissioner, we have seen, is bound to appoint two meetings immediately upon the adjudication of bankruptcy, and at these and every other meeting (with ten days' notice in the 'London Gazette') appointed for that purpose, the creditors may prove their debts on oath. Corporate bodies may make proof by an authorised agent, creditors living at a distance by affidavit, and creditors out of England by affidavit duly verified; and by a special provision, the person effecting a policy of assurance on ships or goods may, though not himself beneficially interested, make proof in case of loss when the person interested is not within the united realm. All debts legally due from the bankrupt at the time of the act of bankruptcy are provable, and also all debts contracted before the filing of the petition for adjudication, though subsequent to the act of bankruptcy; provided the creditor, at the time of the debt being contracted, had *no knowledge* of any act of bankruptcy. Obligees on bottomry and respondentia bonds, and the assured in policies of assurance, are entitled to *make claim*, and when the loss or contingency happens on which the debt depends, they may then prove the debt and receive dividends with the other creditors, as if the contingency or loss had happened before the filing of the petition; and all creditors having claims upon the bankrupt which depend on any contingency may, on application to the court, have a value set upon the contingent claim, and be admitted to prove for the debt thus ascertained. In cases where parties have become bail or sureties for the bankrupt, and have paid the debt or a part thereof (though after the filing of the petition), if the principal creditor has proved the debt under the bankruptcy, such sureties are entitled to stand in the place of the creditor as to the dividends and all rights under the bankruptcy; or where the creditor has not proved his debt, such surety may prove his demand in respect of the payment he has made, so as not to disturb former dividends of the bankrupt's estate; and this, although such surety may have become surety for the bankrupt subsequent to the act of bankruptcy, provided he had no notice of any act of bankruptcy when he became surety. With respect to creditors to whom the bankrupt owes annuity debts, all such creditors may prove for the value of the annuity, which the court is to ascertain, having regard to the original price given, and to the diminution of value from lapse of time between the granting of the annuity and the date of the petition for adjudication. With respect to interest on debts, the general rule is, that no interest is provable unless interest was reserved by contract, either express, or arising by implication from the usage of trade, or other circumstances attending the origination of the debt; but interest is provable if the debt was made payable at a certain time by virtue of some written instrument, or if payable otherwise then from the time of a written demand of payment notifying to the debtor that interest will be thenceforth claimed. Where interest is allowed it is calculated to the date of the petition.

With respect to proof of debts against the partners in a firm, the general rules are, 1st, that as a creditor of the whole firm may, if he please, petition for adjudication against any single partner or any number of partners, he may prove his debt in the same manner; 2nd, a joint creditor of the whole firm may prove against the separate estate of any one partner who is bankrupt, provided there is no partner who is solvent; but if there is a partner who is solvent, then the joint creditors cannot come into competition with the separate creditors of the partner who is bankrupt; 3rd, where there are no separate debts, the joint creditors may of course prove against the estate of the partner who is bankrupt. But for the mere purpose of voting for assignees, joint creditors may prove upon the separate estate, although separate creditors cannot upon the joint estate.

If the whole firm become bankrupt, being indebted to an individual partner, such partner cannot prove against the joint estate in competition with the joint creditors; for as they are his own creditors also, he has no right to withdraw any part of the funds available for the payment of their debts; nor can those partners of a firm who remain solvent prove against the separate estate of a member of that firm in competition with his separate creditors, unless the joint creditors be first paid 20*s.* in the pound and interest.

There are certain classes of creditors which the legislature has peculiarly privileged. The court is authorised to order that the clerks and servants of the bankrupt (which includes travellers) shall receive their wages and salary, not exceeding 30*l.*, and for not exceeding three months, out of the estate of the bankrupt; and they are at liberty to prove for the excess. In certain instances the creditor has a remedy for his debt without proof. Thus, if the creditor of the bankrupt, at the time of the bankruptcy, owes him money, or if there is *mutual credit* between the creditor and the bankrupt (as, for instance, on bills or securities not yet fallen due at the time of the bankruptcy), the creditor is not bound to pay his debt to the estate and prove his counter-debt and take a dividend only with the general creditors, but one debt must be *set off* against the other, and the balance only can be claimed on either side. But in order to be entitled to the benefit of this set-off, the creditor must not have had any notice of the bankrupt's act of bankruptcy at the time when he gave him credit.

In certain cases, also, where the creditor has obtained a security or lien upon the bankrupt's estate, he is allowed to satisfy himself out of it, instead of being compelled to accept a mere dividend. An extent for a debt due to the crown is still more favourably regarded; for as that writ binds the goods of the bankrupt from its *teste* (that is, from the date of its issuing), and as the property in the goods does not pass from the bankrupt till the appointment of the assignees, at which time it vests in them, if the crown extent issues before the appointment of assignees, the crown obtains the property in the goods in preference to the assignees. Other crown process, such as a warrant to levy for land-tax money, obtains a preference for the crown from the time of the *seizure*, in case the assignees have not then been appointed.

A legal mortgage gives the mortgagee a right to retain the property mortgaged until his debt is satisfied, and the assignee of the bankrupt can only redeem it by paying the principal mortgage money, and all interest up to the date of the redemption; and an equitable mortgage, by mere deposit of title deeds, is in general entitled to the same preference. A bonâ fide pledge of personal property stands on the same footing as a mortgage of land, and can only be redeemed by the assignees on payment of the sum advanced. In order however to give such effect to the securities above mentioned, it is necessary that the creditor should have obtained them either before the act of bankruptcy, or, if obtained subsequently, that they should have been obtained without knowledge of any prior act of bankruptcy. The situation of the landlord of a bankrupt tenant is peculiar. He has a right to distrain all goods on the premises for his rent, even though the demise itself be not made till after the act of bankruptcy. If he neglects his right of distress he must then prove, and come in with the common creditors; and the distress, if made subsequent to the act of bankruptcy, is only available for one year's rent up to the filing of the petition, and the landlord must prove the residue of his demand like another creditor.

Assessed taxes, up to the 5th day of April next after the bankruptcy, not exceeding one year's assessment, are to be paid out of the estate; and the bankrupt is relieved from further assessment in respect of articles previously kept for trade purposes and duly surrendered and sold under the bankruptcy and not subsequently used.

When an officer of a friendly society becomes bankrupt, monies of the society in his hands are to be paid over to the society out of his estate in preference to other claims.

7. *Of the Effect of the Bankruptcy on the Rights of Third Parties.*—The general rule is, that all the property of a bankrupt vests in his assignees for the benefit of the creditors *from the time of the act of bankruptcy;* from which it follows that all dispositions made by the bankrupt of his property after that time are void—a doctrine which occasioned much hardship in many instances to persons who had dealt with the bankrupt in ignorance of his having committed an act of bankruptcy, and which has therefore been materially mitigated and qualified by legislative provisions. It is accordingly provided, that all bonâ fide payments by or to, and all bonâ fide conveyances by, and all contracts, dealings, and transactions by and with the bankrupt, made before the filing of the petition for adjudication, and that all executions against the bankrupt's land bonâ fide executed by seizure, and all executions against the goods of a bankrupt bonâ fide executed and levied by seizure and sale before the filing of such petition, shall be deemed to be valid, notwithstanding any prior act of bankruptcy, provided the person so paying to or dealing with the bankrupt, or at whose suit such execution issued, had not at the time of so paying or dealing, or at the time of sale under such execution, notice of any prior act of bankruptcy, and also provided that there be no fraudulent preference of any such creditor. This protection is afforded on condition that the party protected has no notice of an *act of bankruptcy* at the time of the payment or dealing, &c., and consequently no transaction that is itself an act of bankruptcy is thus protected. In order however to deprive the party of the benefit of the act, he must have notice strictly of some act of bankruptcy having been committed. Mere knowledge that the bankrupt is in *embarrassed circumstances* at the time of the payment will not take the case out of the protection of the statute; and unless a petition

for adjudication be filed within twelve months, all bonâ fide purchases for value are protected.

When none of the above statutory exceptions and qualifications take effect, the general rule applies, with all its consequences, that the assignees are invested with the property of the bankrupt, by relation, back to the act of bankruptcy. The doctrine that the adjudication when made, has relation back to the act of bankruptcy, has no application against the crown; and therefore intermediate seizures by the crown of the bankrupt's goods are valid. And as a party who is sued at law by a bankrupt cannot defend himself, by showing that the bankrupt, before the action, has committed an act of bankruptcy, it follows that all payments actually enforced at law by the bankrupt, before the adjudication, are good payments, since it would be a glaring injustice to allow the assignees to recover them a second time.

Not only is all the property to which the bankrupt himself has a right applicable towards the payment of his creditors, but there are instances in which *effects of other parties* in his custody, which could not have been retained by the bankrupt had he not become bankrupt, will vest in his assignees under the *fiat*. The present enactment on this subject, the Bankrupt Law Consolidation Act, 1849, § 125, is levelled at the mischief occasioned by allowing the use of other persons' property to be granted with impunity to a failing trader, who is thereby enabled to assume a deceitful appearance of wealth, and obtain factitious credit with the world. Accordingly, if any bankrupt, by the permission and consent of the owner, shall have in his possession, order, or disposition, any goods or chattels whereof he was reputed owner, or whereof he had taken on himself the sale, alteration, or disposition as owner at the time of his bankruptcy, the court may sell the same for the benefit of the creditors. This provision applies only to goods and chattels, such as furniture, utensils in trade, stock, bills of exchange, &c. Ships are specially provided for by the Merchant Shipping Act, 1854, § 72, which enacts that no registered mortgagee of any ship, or of any share therein, shall be affected by any act of bankruptcy by the mortgagor subsequent to the date of the record of such mortgage. Interests in property of a real nature, including fixtures, are not affected by it. The main difficulty, which has occasioned much litigation as to the cases within this clause, is in deciding whether the bankrupt was or was not the *reputed owner* of the property at the time of his bankruptcy, which is a question of fact determinable by a jury, according to the circumstances of each particular case. Where the bankrupt has once been the real owner, but has sold or disposed of the goods, the circumstance of his still remaining in possession of them raises generally a presumption that he possesses them as reputed owner; but where the bankrupt has the possession of the goods without ever having been the real owner, it will require stronger evidence to show his reputed ownership at the time of the bankruptcy. The distinctions upon the subject are some of the nicest which occur in the decisions of the courts. Where the purchaser of wines transferred them to a particular bin in the vendor's cellar, had each bottle sealed with his own seal, and had an entry made in the vendor's books, it was held that these precautions prevented the wines from falling within the operation of the clause. But in a case, where the purchaser simply marked certain casks in chalk with his initials, and gave no notice to the warehouseman, the decision was to the contrary. If a bond is assigned over by the obligee, it must be delivered to the party to whom it is assigned, and notice must be given to the debtor, otherwise it will pass to the assignees of the obligee in case of his bankruptcy. And it is the same as to the assignment of a policy of insurance or other chose in action. Bills discounted by a banker are in effect purchased by him, and they therefore pass with the rest of his property to his assignees in the event of his bankruptcy; but bills which are not due, and are entrusted by a customer to his banker for collection (entered short), though indorsed, remain the property of the customer, since the banker is a mere agent for the purpose of receiving the amount when they become due. But it is otherwise if the bills, though not due, are paid in by the customer, and treated absolutely as *cash*. Property which the bankrupt holds merely as trustee, or as executor or administrator, or as a factor, or which is placed in his hands merely for some particular purpose, will not pass to his assignees as being in his reputed ownership. Goods which a bankrupt receives on the terms of sale or return are held to be in his reputed ownership, and to pass to the assignees; but where the bankrupt had received goods the evening before his bankruptcy, and in fact never unpacked them, it was held the owner might reclaim them. If a trader have mortgaged his goods, but remain in possession of them, they will pass to the assignees; and this used to be the law with respect to the mortgage of a ship.

8. *Arrangements between Bankrupts and their Creditors under the control of the Court, or by deed; and composition of bankruptcy.*

a. Under the control of the Court.—A trader unable to meet his engagements may, by petition to the Court of Bankruptcy within the district of which he has resided or carried on business for the previous six months, set forth the reasons of such inability, and pray that his person and property may be protected from process until further order. This petition must be in the form provided by the Bankrupt Law Consolidation Act, 1849, Schedule Aa, and be supported by affidavit. Thereupon the court may make such protecting order, and if he be already in custody for debt may, except in certain specified cases (Bankrupt Law Consolidation Act, 1849, § 211), order his release. The court then appoints a private sitting and an official assignee; and if sufficient cause be shown, may direct the petitioner's estate and effects to be seized by the messenger of the court, or to be held and received by such official assignee. Fourteen days' notice in writing of this private sitting must be given to every creditor; and ten days before it is held the petitioner must file a full account and statement of his affairs, and therein set forth such proposal as he is able to make for the payment or compromise of his debts and liabilities. At the sitting the creditors are to prove their debts, and the petitioner is to attend and be sworn to his account and statement, and may be examined thereon. If three-fifths in number and value of the creditors, who have proved for amounts exceeding 10*l.*, assent to the proposal or to any modification of it, the court appoints another sitting for its confirmation, to be held not earlier than fourteen days from the first sitting. Of this second sitting seven clear days' notice in writing must be served upon every creditor not present in person or by agent at the first sitting; and if at such second sitting the proposal assented to at the first sitting be accepted by three-fifths in number and value of those creditors who have debts to the amount of 10*l.*, the terms of the proposal are reduced into writing, and the creditors are to sign the same. The court after hearing any opposing creditor who desires so to be heard, may, if the resolution or agreement appear to the court to be reasonable and proper, approve and confirm it. It is then filed and entered of record, and a certificate is issued by the court to the petitioner; whereupon is endorsed from time to time a protection from arrest binding upon all creditors who had notice of the sittings. Upon this approval and confirmation the petitioner's estate vests in the official assignee as fully as in bankruptcy, either solely or conjointly with any persons that may be named for that purpose in the resolution. When the terms of the resolution or agreement have been fully carried out, the court gives to the petitioner a certificate thereof, that has the same effect as a certificate of conformity under a bankruptcy, except as to debts contracted wholly or in part by reason of any manner of fraud or breach of trust, or without reasonable probability at the time of contract of being able to pay the same, or by reason of any judgment in any prosecution for breach of the revenue laws, or in any action for breach of promise of marriage, seduction, criminal conversation, libel, slander, assault, battery, malicious arrest, malicious trespass, maliciously suing out a fiat in bankruptcy, or maliciously filing or prosecuting a petition for adjudication of bankruptcy. If the petitioner does not attend the sittings of the court, or if he fails duly to file a true and complete account, or if neither his proposal nor any modification thereof be assented to at the first sitting, or any adjournment thereof, or if it appear that any debts have been contracted under such circumstances as would exclude the operation of the certificate as above-mentioned, or that the petitioner's affidavit was wilfully untrue, or that his proposal was unreasonable, or that his petition was unduly delayed, or if within three months of its presentment he wrongfully assigned or made away with any portion of his estate and effects, or voluntarily allowed his goods to be taken in execution, the court may adjudge him thenceforth a bankrupt and proceed accordingly.

b. By Deed.—Any deed or memorandum of arrangement between a trader and his creditors, signed by or on behalf of six-sevenths in number and value of those creditors whose debts amount to 10*l.*, touching such trader's liabilities and his release therefrom, and the distribution of all his estate among all his creditors rateably, is obligatory upon those creditors who have not signed it, and is not liable to be disturbed by any prior or subsequent act of bankruptcy. But such deed or memorandum does not thus bind a creditor until the expiration of three months from his receiving from the trader notice of his suspension of payment, and of the deed or memorandum, unless the court for the district in which the trader has resided or carried on business for six months next preceding his suspension, shall in the meantime certify that the deed or memorandum has been duly signed, and the creditors had fourteen days' notice of the trader's intention to apply for such certificate. When the trustees or inspectors under the deed or memorandum (if any be appointed thereby), or in the absence of such appointment, when any two creditors are satisfied that the deed or memorandum has been duly signed, and certify the same to the court in writing, their certificate is filed with the registrar, and becomes primâ facie evidence of such due signature. This certificate is to have appended to it a full and particular statement of the trader's debts and of his creditors, verified by the trader's affidavit; and if there be in it, through fraud or culpable negligence, any false statement or omission, the trader will be deprived of all benefit to be derived by him under the arrangement. The rights of the creditors are adjusted as in bankruptcy.

c. Composition of Bankruptcy.—If any bankrupt, after passing his last examination, call a meeting of his creditors, giving twenty-one days' notice thereof in the 'London Gazette,' and then make an offer of composition that nine-tenths in number and value of his there present creditors agree to accept, and if such proposal be again so accepted at a second meeting similarly convened, the court, upon such acceptance being notified to it in writing, and upon payment of such sum as it may direct, annuls the adjudication and dismisses the petition, and every creditor is bound by the composition. Special regulations as to voting in respect of compositions, are prescribed by the Bankrupt Law Consolidation Act, 1849, sec. 231.

9. *The Constitution of the Court of Bankruptcy.*—The court of bankruptcy is a court of record, and for all purposes of bankruptcy administers both law and equity. Its ordinary judges are commissioners appointed under the great seal. The court of appeal is composed of the lords justices of appeal in Chancery. The commissioners have separate jurisdiction limited by their respective districts. The London district comprises the Metropolitan counties, and Sussex, Hampshire, and part of Wiltshire. Its court is presided over by one chief commissioner at a salary of 2500*l.* per annum, and by four commissioners at salaries of 2000*l.* per annum. The country districts are seven in number, and their courts are held respectively at Manchester, Leeds, Liverpool, Birmingham, Bristol, Exeter, and Newcastle-upon-Tyne. To each of the first two above-mentioned districts are attached two commissioners; to the last five one commissioner only is attached. Each country commissioner has a salary of 1800*l.* per annum. To each court is also attached one registrar in respect of each commissioner. The London court has one chief registrar who enjoys a salary of 1200*l.* per annum, and four registrars at 1000*l.* per annum each; besides a registrar who attends the court of appeal. Country registrars receive salaries of 800*l.* per annum. To each court are also attached certain official assignees who are appointed by the Lord Chancellor, and must be selected from the class of merchants, brokers, accountants, or traders. Ten such assignees are attached to the London court, and eighteen are attached to the country courts. Their remuneration chiefly consists of a per-centage upon the assets collected. The emoluments of the London assignees average from 1000*l.* to 1200*l.* exclusive of office expenses. In the country their emoluments are less and the variations greater.

Messengers and brokers are also attached to the various courts. The expenses of the official staff and machinery employed in bankruptcy is very great, and in the smaller cases very much out of proportion to the assets actually distributed among the creditors. In the course of the years 1853, 1854, and 1855, the London and country commissioners adjudicated on 2138 petitions. In 583 of these cases no dividend had been paid, but of these only 40 were above 500*l.* Of the others the amount of assets collected had been 1,978,325*l.*, of which 1,073,386*l.* had been distributed in dividends. The solicitors' charges had been 235,513*l.*; the commissions, &c., of the official assignees were 85,586*l.*; the charges for stationery, postage, &c., were 12,622*l.*; other charges, including fees to brokers, messengers, travelling expenses, &c., amounted to 294,501*l.*, and the balance in hand was 278,455*l.* Thirty per cent. or rather more of the assets are consumed by costs.

The number of certificates granted by the London Court of Bankruptcy during the five years ending July 5, 1858, was as follows, viz.: first class certificates, 307; second class certificates, 1176; third class certificates, 467; certificates suspended, 693; certificates refused, 37; adjournment of bankrupts' examinations *sine die*, 404.

A valuable report was presented to parliament in 1854, whence much information as to the working of the present system of bankruptcy may be obtained.

A steady and gradual diminution of the business of the court has been for some years progressing, and the better class of estates are now almost universally wound up and distributed out of bankruptcy. To remedy the evils observed, and to render the constituted court thoroughly effective, a bill has been (February 7, 1859) introduced into the House of Lords by the Lord Chancellor for amendment of the law of debtor and creditor, and the procedure for administering bankrupt and insolvent estates. It is thereby proposed to amalgamate the present bankruptcy and insolvency jurisdictions, and to extend to the non-trader the liabilities and benefits hitherto confined to traders. Imprisonment for debt by way of ordinary remedy for its recovery is to be abolished. Lord John Russell also (February 15, 1859) introduced to the House of Commons a somewhat similar measure, and there can be now little doubt of great alteration and improvement being effected in this important branch of administration.

The subject of the bankruptcy and winding-up of joint-stock companies under the numerous statutes relating to them, will be more conveniently discussed under the title COMPANIES, JOINT STOCK, WINDING-UP.

Proceedings under the act for facilitating arrangements between debtors (*not being traders*) and their creditors, 7 & 8 Vict. c. 70, though within the exclusive jurisdiction of the court of bankruptcy, will be more fitly considered under the title INSOLVENCY.

The Irish law of bankruptcy was gradually assimilated to the English law by several acts, 6 & 7 Will. IV. c. 14; amended by 1 Vict. c. 48, and 2 & 3 Vict. c. 86; and recently by the 20 & 21 Vict. c. 60, the various laws relating to bankrupts and insolvents in that part of the kingdom have been consolidated, and the administration thereof committed to a new court called 'The Court of Bankruptcy and Insolvency' (20 & 21 Vict. c. 60).

See upon the subject of bankruptcy, Blackstone's 'Commentaries' edited by Dr. Kerr, vol. ii. p. 484, et seq.

In 1841 an act was passed by Congress to establish a uniform system of bankruptcy throughout the United States of North America. The act came into operation in 1842.

In June, 1838, the French law of 1807 on bankruptcy and insolvency was abrogated, and an entirely new law was promulgated, which now forms Book III. of the Code de Commerce (Des Faillites et Banqueroutes).

BANKRUPT LAWS OF SCOTLAND. In the earliest records of the law of Scotland we find that debtors were entitled to a discharge on a judicial cession of their goods to their creditors. This proceeding, which still subsists in Scotland, we shall consider in detail under the head of CESSIO BONORUM; and only remark here, firstly, that it has always been a general remedy, and not confined to traders or any other class; and secondly, that it is essentially an insolvent's remedy, and, although it relieves the *person* from liability, it leaves the liability still subsisting as to the *property* of the debtor.*

The first statute which introduced the principle of a total discharge to the debtor was passed in 1772. All persons might be brought under it, and the funds were held and distributed by an assignee, under direction of the Court of Session. In 1783, the management of the estate was removed from this judicial control, and placed, as it has continued ever since, entirely in the hands of the creditors themselves, and subject to review by the court only on points of law. At the same time, however, the remedy was restricted to *traders*; a restriction which continued in force till 1856. The law of bankruptcy, which had in the meanwhile undergone a variety of successive improvements, in that year was expanded in several most important particulars, and a consolidation act was passed (19 & 20 Vict. c. 79), which with a short amending act of the following year (20 & 21 Vict. c. 19), now comprises the whole of the statute law on the subject of *Sequestration for Debt*, as bankruptcy is styled in Scottish legal language.

The law of bankruptcy in Scotland is, however, by no means limited to the proceedings connected with a sequestration. The commission of an act of bankruptcy constitutes what is called *notour* (that is, notorious) bankruptcy; a status which has a retrospective as well as prospective effect, and which subsists until insolvency ceases. It has always been the law, that any person might be rendered notour bankrupt, although traders only could obtain as a consequence the subsequent benefit of sequestration. The general operation of an act of bankruptcy, constituting notour bankruptcy, consists, 1. In its annulling all preferences granted to particular creditors (except in the shape of payment in cash) within sixty days prior to its commission. 2. In its establishing a "*pari passu* ranking of diligence;" that is, an equality of sharing in the proceeds of all forms of execution against the property of the debtor, amongst all persons who sue out such executions within the period of sixty days before, and four months after, the commission of the act of bankruptcy.

The acts of bankruptcy which constitute this status of notour bankruptcy are, except one, all of a judicial nature. The first is sequestration itself, or an adjudication of bankruptcy in England or Ireland. These are sufficient, although the party be not really insolvent; all the other acts must be conjoined with actual insolvency to have effect. Notour bankruptcy then may be constituted by actual insolvency concurring with imprisonment, or at least arrest on a judgment debt, or the absconding of the debtor to avoid arrest after receiving notice to pay such a debt, or by a sale of his goods under a *poinding* (*fi. fa.*), or *sequestration for rent* (distress), or by his application for the benefit of *cessio bonorum*. Where he is protected from imprisonment by privilege, or it is otherwise impossible, execution against the goods or real estate after notice to pay will suffice before the stage at which they are actually sold. The sole case in which a merely private proceeding on the part of the debtor will amount to an act of bankruptcy is where, being insolvent, he takes refuge for twenty-four hours in the *Sanctuary*—a space of ground round Holyrood Palace, which still retains its royal privilege of protecting against arrest for debt. In the case of a company or partnership, any of the above-mentioned forms which are applicable will render it notour bankrupt, and the same effect will be produced by any of the partners being rendered notour bankrupt in respect of a company debt.

We proceed now to the consideration of a sequestration for debt, or adjudication of bankruptcy. This remedy is now of the widest possible application; being available to every one who is subject to the jurisdiction of the supreme courts of Scotland. It includes companies and partnerships, and even extends to the property of persons deceased. It may be applied for by the debtor himself, and it is not necessary that he should be notour bankrupt, but he must obtain the consent of creditors to the same amount as would entitle them to petition of themselves. This amount is, 50*l.* for one creditor, 70*l.* for two, and 100*l.* for three or more. It is not necessary that these debts should be liquidated, but they must not be contingent. If creditors petition for sequestration without the consent of the debtor, it is requisite that he should have been made notour bankrupt within four months prior to the petition. The estate of a deceased debtor may be brought into bankruptcy if he had given written authority for its being done, or if

* Fraud was not reckoned in Scotland an essential element in the description of a bankrupt. The Scottish name was *Dyvour*, a term the etymology of which lawyers have not hitherto been very successful in tracing; but it seems to be derived from *devorer*, French, to consume one's substance, and if so it is synonymous with the former appellation in English law, *decoctor* or spendthrift. The most ancient Scottish appellation was *Bare-man*, and the cessio bonorum was called "the bare-man's process." This term, indeed, conveys the generic idea without any adventitious quality.

creditors to the requisite value petition, although he was not notour bankrupt. But if he was not, or unless his representatives consent, six months must elapse after his death before the award of sequestration (the adjudication) can take place.

It is not necessary to show that the debtor has assets to any particular amount. But if in the course of the proceedings it appears that the assets fall short of 100*l.*, the court has power, on application of a majority of the creditors, to order that the discharge (certificate) shall be equivalent only to a discharge in a cessio, which, as already mentioned, leaves the debtor's after-acquired property still liable.

One of the most valuable improvements made in the recent act, lies in the authority given to the sheriffs of counties (judges of county courts) to award sequestration in the case of debtors who have resided or carried on business for a year within their jurisdiction. Formerly it could be awarded only in the Court of Session. In all cases, indeed, it still *may*, and where the debtor has not spent the requisite time in one county it still *must* be applied for in that Court. Yet it appears from the returns for the first year after the change was introduced (1856-7), that seventy-five per cent. of all the sequestrations awarded were applied for to sheriffs of counties; and it is understood that the proportion is still increasing. But in whatever court the sequestration is awarded, the whole of the subsequent judicial procedure takes place in the county in which the debtor resided or carried on business, or which may be most convenient for the creditors. This is determined by the Court of Session, when the preliminary proceedings have taken place before it.

If the petition is by the debtor, or with his consent, no service is requisite, and sequestration is at once awarded; but if by creditors without the debtor's consent, it must be served upon him with notice to appear on a day fixed, not less than six nor more than fourteen days after service. In the event of his being out of Scotland, service is effected by publication in a register for that purpose kept in Edinburgh, and twenty-one days are allowed for appearance; in either case, notice is also given by advertisement in the 'Edinburgh Gazette.' On the day appointed, the debtor may oppose the petition on legal grounds, or may pay the petitioning creditors' debts, together with the debts of any other creditors who have appeared. But if he do not, or if his opposition be not well founded, sequestration is awarded. No appeal lies against this order, and the procedure consequent on it cannot be delayed; but any creditor, or the debtor himself (if he had not consented), may, within forty days, apply to the Court of Session to recall the sequestration. In considering this application the Court exercises a large discretion; not only in respect to the strict legality of the proceedings, but in respect to their fitness. Even after the forty days, nine-tenths of the creditors have the power, at any time, of applying for recall.

The award of sequestration vests the estate in the creditors; but it must be instantly advertised in both the London and Edinburgh 'Gazettes,' and a notice of it must be inserted in a register of rights affecting land kept in Edinburgh. This last operates as notice to all persons dealing with the debtor's real estate. The personal property may, if it is thought necessary, be taken possession of by an officer appointed by the court, and held by him till the first meeting of creditors.

This meeting is fixed in the judge's order awarding sequestration, and must take place not less than six nor more than twelve days after the appearing of the advertisement of sequestration in the Gazettes; the place and time for holding it are notified in the same advertisements. At this meeting the creditors may resolve (by a majority of four-fifths in amount of the claims) to wind up the estate under a deed of arrangement; if they do so, they apply to the sheriff for an order to stay proceedings for a period not exceeding two months. Within this period they must present to the sheriff a deed of arrangement, signed by four-fifths in number and value of the creditors; and the sheriff after ordering such intimation as he may think requisite, and hearing any parties who oppose, may approve or disapprove of it. If he approves, the deed is rendered binding on all the creditors, and the sequestration is at an end; if he disapproves, the sequestration proceeds.

But if the creditors do not resort to this course, the first business of the meeting is to elect a trustee (assignee); this is done by a majority (in value of debts) of those present, or represented by proxies. The trustee may be a creditor, provided he has no special interest opposed to that of the general body of creditors; in the larger bankruptcies an accountant is generally selected. The debts of the creditors voting are proved in the presence of the meeting itself, by being stated in writing in the statutory form, and accompanied with proper vouchers and with an affidavit of their truth. Primâ facie proof is all that is at this stage required. The decision of the meeting is liable to review by the sheriff, either on the ground of objection to the candidate elected, or on the ground of votes in his favour having been wrongly admitted. Frequently the sheriff's decision is obtained on the spot, for it is in the power of any two creditors by previous requisition to obtain his attendance at the meeting; but if the question be of difficulty, or he is not present at the meeting, his judgment may be obtained within a few days after. No appeal lies from his judgment. No costs come out of the estate; they are paid by the unsuccessful parties.

In like manner the creditors next proceed to elect a sort of council of the trustee, consisting of three persons, necessarily creditors, who are designated commissioners. They may next, if they think fit, decide (by a majority in number and value) on granting or renewing a protection from arrest to the bankrupt. Up to this period, the bankrupt may have enjoyed such protection granted by the sheriff, on cause shown; but from the date of the first meeting of creditors, the question of continuing it rests wholly with them. Lastly, the meeting may (by a majority of four-fifths in value) vote an allowance to the bankrupt till the time for payment of the second dividend, not exceeding the rate of three guineas per week.

When the trustee's election has been duly declared, he must give a bond of security to such amount as shall have been previously fixed by the meeting of creditors, and with sureties approved by them. When this is done, he obtains from the sheriff a formal appointment to his office, which serves for his title in all suits and other proceedings. He may be removed at any time by a majority in number and value of the creditors, or by the Court of Session, on application of one-fourth in value of the creditors, and on sufficient cause shown. The commissioners may, in like manner, be removed by the creditors. On such an event occurring, a new trustee or commissioner is elected in the same manner as at the first election.

The trustee's first duty is to take possession of the whole of the bankrupt's estate, and to make out an inventory, list of creditors, &c. In this he has the assistance of a statement by the bankrupt of his affairs, which he is bound to submit to the first meeting of creditors. But neither the trustee nor the bankrupt are entitled to professional assistance in performing this duty, at least at the cost of the estate. The trustee must also apply to the sheriff to name an early day for the bankrupt's examination. The day and place are advertised, and the examination is conducted in presence of the creditors, any of whom may put questions; but it does not, except on special application, take place in public. The bankrupt may correct his statement of affairs, and must then swear to its truth. Any of his family, clerks, shopmen, or other persons who may be supposed able to give information as to the estate, may likewise at any time be examined. The examination is before the sheriff, and on oath.

The trustee then proceeds to realise the bankrupt's estate; in this he is bound to follow any directions the creditors may think fit to give, and he is aided by the advice of the commissioners. At the same time he takes preparatory steps for the payment of the dividends. These are made at fixed periods, without any order of court. The first is made six months after the sequestration, the second ten months, and each succeeding dividend three months after that preceding. Claims must be given in to the trustee two months before the time for payment of the first dividend, a period of which ample notice is given by advertisements and circular letters. They must be accompanied with an affidavit, and sufficient legal proof of the debt; but personal attendance of the creditor is not necessary, unless his proof be so defective as to make it necessary that the trustee should examine him. The trustee considers the proofs of each debt, admits or rejects them, or calls for further evidence, as he may think proper, and notifies the result to each creditor. A creditor may appeal either against his own rejection, or against the admission of another; such appeal is taken either to the sheriff or Court of Session. The commissioners audit the trustee's accounts, and fix the sum applicable to dividend. This is paid, on the day appointed, to those whom the trustee has admitted; a proportion being retained to meet the claims which he has rejected, and on which appeal has been brought.

A similar procedure is followed in making each succeeding dividend. A creditor whose claim has been once admitted does not, however, need to renew it; he receives the subsequent dividends as matter of course. Creditors who have not claimed in time for the first dividend, receive an equalising dividend on the occasion of the next, if there are funds to pay it. The commissioners have power to postpone making a dividend till the arrival of the next statutory period for so doing; and the creditors may, on the other hand, shorten the statutory intervals between each. Twelve months after the sequestration they may, by a majority of three-fourths, sell their remaining interest in the estate by auction.

At any time after his examination, the bankrupt may apply to the sheriff for his *discharge* (certificate); but he must in all cases produce a report by the trustee on his conduct, and this report the trustee is not bound to give till five months after the sequestration. Further, till six months after the sequestration, the bankrupt must produce the consent of every creditor; and, until the completion of two years from the sequestration, he must produce the consent of a gradually diminishing majority in number and value of his creditors. The petition for discharge is advertised in the 'Gazette,' and intimated to each creditor; and the court, after hearing any opposition that may be made, grants or refuses it. There is no division of discharges into classes. The bankrupt receives the surplus, if any, of his property, but no sum for re-establishing him in business.

Instead of the ordinary course of dividing the estate, the bankrupt may offer a composition; it must be accompanied with security for its payment. Ample notice must be given to the creditors, and the trustee must send to each an estimate of the amount the estate is likely to produce. A meeting is specially called to consider the proposal, and four-fifths in value are required to authorise its acceptance. If accepted, the sheriff, or Court of Session, may hear any objectors, and unless the offer is found reasonable by the court the acceptance is void. If found reasonable, the bankrupt obtains his discharge.

When the whole estate has been divided, or a composition accepted, the trustee applies for his discharge. He lays his books and accounts before a meeting of creditors called for the purpose, who may express their opinion upon them. This opinion is laid before the sheriff; and he, after hearing any objection, may grant the trustee his discharge, and order his bond of security to be returned to him. The unclaimed dividends are placed in a bank; the books and papers are transferred to a registry kept by the accountant in bankruptcy. The trustee is paid by a commission on the assets collected, the rate of which is fixed by the commissioners at each audit prior to making a dividend, and he receives authority to take credit for the amount. He may, if dissatisfied, appeal to the sheriff. The commission averages about four per cent. It may be mentioned that the whole of the legal and miscellaneous expenses chargeable on the estate average about six per cent. more. The commissioners act gratuitously, and no solicitor can be employed at the cost of the estate, except to conduct law-suits sanctioned by the creditors.

The accountant in bankruptcy is a public officer, whose duty it is to obtain and file all returns which trustees on bankrupt estates are bound to make at regular periods. No money passes through his hands, but any irregularity which he may detect, either in the accounts or in the general proceedings, may be brought by him under the notice of a meeting of creditors, and, if necessary, of the Court of Session. He annually makes out a return, showing what has been done in each sequestration, and including a general report on the working of the act.

It has been seen that the proceedings in a Scottish bankruptcy are wholly extra-judicial, except where the creditors require the interposition of the *power* of a court of justice, or where an appeal is taken from their determination, or where authority is required to enable a part to bind the whole. In such cases the application may generally be to the local judge: in some cases either to him or to the Court of Session. In some cases of importance also, an appeal is given from the local judge to the Court of Session. Most of the functions of the Court of Session in matters of bankruptcy are performed by a single judge, called the Lord Ordinary on the Bills, who sits as well in vacation as during the sittings of the court, and in vacation *all* proceedings may be taken before him. No appeal has the effect of staying the regular proceedings in the bankruptcy.

[*Treatise on the Law of Bankruptcy in Scotland*, by John Boyd Kinnear, Advocate and Barrister-at-Law, 1857, and Supplement, 1858.]

BANKS FOR SAVINGS. [SAVINGS BANKS.]

BANNER. Dr. Johnson, instead of a definition of this word, or a description of the thing signified by it, has given only an imperfect catalogue of its synonyms: *flag, standard, military ensign, streamer*, and derives it from the Welsh *banair*. The etymology is uncertain, but it is probably derived from the old German *ban* or *fan*, to lead on, whence the Germans themselves have derived *fhan*, a standard, or banner. It is not improbable that it may come at once to us from the Anglo-Saxon *banegn*, an ensign, that is, the sign or rallying-point of the band or troop which bears it. A *banner* we conceive to be essentially a piece of drapery attached to the upper part of a pole or staff. This generally hangs loose, but is sometimes fixed in a slight framework of wood. Before, however, the idea of *banner* is complete, we must regard this simple piece of workmanship as being in some way indicative of dignity, rank, or command, or as being carried on some occasion with which ideas of dignity are connected, as in processions in time of peace, or in the field in time of war.

The size and form are but accidents. In fact, it has been made to assume all the varieties of which so simple an instrument is susceptible. When banners are displayed at the same time by persons of different ranks, the size has often borne relation to the respective rank of the parties.

The drapery of a banner is usually made of the most costly stuffs—velvet or silk—but the material most commonly used is a kind of soft silk called taffeta. Sometimes it is quite plain, and of one uniform colour. A white banner was anciently borne in the English army. One of the knights at the siege of Carlaverock, a castle in Scotland, in the wars of Edward I., carried a plain red banner; but they were often richly ornamented with tassels and fringes, and generally there is wrought upon them some figure or device which has reference to the person, the community, or the nation by whom the banner is raised, or to the purpose or occasion of its being displayed.

Other terms by which a banner is called, are—

Standard, by which is meant the most considerable banner of an army, or the national banner when displayed in the field, or a banner set up by some prince, or other chief, as a rallying-point for his friends.

Colours, the banners now borne by particular regiments.

Flag, a banner on board a ship, generally employed as a signal.

Pendant is a narrow flag with a long streaming tail, and has been adopted by all modern nations to denote the vessel which carries it to be a national vessel, or man-of-war.

Streamer is a poetic word, which seems to be used for any species of floating banners.

Ensign is a word formed on the idea of the banner displaying *insignia* which belonged to a particular person, or collection of persons. It was formerly used where we now say *colours*; and the officer called an *ensign* was originally the *ensign-bearer*. It is also applied to the national colours worn by vessels over their stern.

Pennon, another mode of writing pendant.

Pensil, or *Pennoncille*, a small pennon.

Bannière-quarrée, where the drapery was square.

Guidon is now used for the little banner of a regiment.

Gonfannon is properly appropriate to the banner of the pope or of the church.

Oriflamme, was the name of the great national standard of France, only unfurled on important occasions.

Of all these, however, the word *banner* is used by most writers and speakers as a synonym, or as a generic term, of which the other words indicate particular species. We shall therefore bring together in this article much of the information we have been able to collect on a subject to which little attention has hitherto been paid, but which is connected with all our chivalry and much of our poetry, and is not without its share of historical importance and national interest.

The earliest mention of standards is in Numbers ii. "every man . . . shall pitch by his own standard, with the ensign of their father's house," and Egyptian paintings and Assyrian sculpture show us what those ensigns probably were, namely, representations of some object, beast or bird, or some arbitrary symbol, fixed on the top of a pole; and these show also that there were at least three kinds of them, those of the monarch, those of houses or families, those of tribes, and the great standards which served as rallying-points for the whole host, as well as for marking the line of march or the places of encampment. The military standards of the Greeks and Romans were of a similar character, the standard of the Athenians was an owl, which they also impressed on their coins, that of the Thebans a sphinx. The standards of the Romans were carvings in metal or wood; the eagle, or some other figure, elevated at the end of a tall lance or pole. The forms of them are known to us by the representations of them on medals, or the common coinage of that people. The Persian standard described by Xenophon ('Anab.' i. 10) was a golden or gilded eagle, raised on a spear or pole. We have few such representations of the military ensigns of other nations of antiquity, and nothing, it seems, which can authorise us to suppose that banners, in the sense in which the term has been here defined, were in use among them.

But we find them in use among the modern nations of Europe from a very early period. The first notice of them in English affairs is by Bede, who, when he relates the first interview which Augustine and his followers had with Ethelbert, king of Kent, says that they approached the king bearing banners on which were displayed silver crosses, and the picture of Jesus Christ, and chanting, as they went along, prayers for his welfare, and that of his people. They were then living in the Isle of Thanet; and when the king had assigned them habitations in Canterbury, they entered the city in procession, carrying their little banners chanting halleluiahs, and praying for the blessing of God on the city which received them.

Thus early were banners used in religious affairs, to the pomp and splendour of which they have lent their aid in all later times, as in Catholic countries they still continue to do.

All the monasteries in England had banners laid up in their wardrobes, to be produced on the great anniversaries, or on the anniversary of the particular saint in whose honour the church was founded. These were sometimes, as we shall see, allowed to be carried out of the monastery, and displayed in the field. At Ripon, for instance, there was the banner of St. Wilfrid; at Beverley, the banner of St. John of that town. Both these were displayed in the field at Northallerton in the reign of Stephen. We find, also, Edward I. paying 8½*d*. a day to one of the priests of the college of Beverley for carrying in his army the banner of St. John, and 1*d*. a day while taking it back to his monastery.

Sometimes the banners of the religious not only displayed a representation or symbol of a particular saint whom they held in especial honour, but some relic of the saint composed a part of the banner. This was the case with the banner of St. Cuthbert at Durham. Of this banner there is a particular and authentic description in a very curious little volume, entitled 'The Ancient Rights and Monuments of the Monastical and Cathedral Church of Durham,' 1672, which we shall here transcribe:—"The prior caused a goodly and sumptuous banner to be made, with pipes of silver to be put on a staff, being five yards long, with a device to take off and on the pipes at pleasure, and to be kept in a chest in the feretory, when they were taken down, which banner was showed and carried in the said abbey on festival and principal days. On the height of the overmost pipes was a fair pretty cross of silver, and a wand of silver, having a fine wrought knot of silver at either end, that went underneath the banner-cloth, whereunto the banner-cloth was fastened and tied; which wand was of the thickness of a man's finger, and at either end of the said wand there was a fine silver bell. The wand was fastened by the middle to the banner-staff hard under the cross. The banner-cloth was a yard broad and five quarters deep; and the nether part of it was indented in five parts and fringed, and made fast all about with red silk and gold; and, also, the said banner-cloth was made of red velvet, on both sides most sumptuously embroidered and wrought with flowers of green silk and gold; and in the midst of the said banner-cloth was the said holy relique and corporax cloth [this was the corporax cloth with which St. Cuthbert in his lifetime had been used to cover the chalice when he said mass] inclosed and placed therein: which corporax cloth was covered over with white velvet, half a yard square every way, having a red cross of red velvet on both sides over the same holy relique, most artificially and cunningly compiled and framed, being finely fringed about the skirts and edges with fringe of red silk and gold, and three little fine silver bells fastened to the skirts of the said banner-cloth, like unto sacring bells; and being so sumptuously finished and absolutely perfected was dedicated to holy St. Cuthbert, to the intent and purpose that the same should be presented and carried always after to any battle, as occasion should serve; and which was never carried or showed at any battle, but, by the especial grace of God Almighty, and the mediation of holy St. Cuthbert, it brought home the victory."—pp. 42-44. This banner was made in the year 1346, but there had been a banner of St. Cuthbert before; for in the wardrobe accompts of Edward I. (1299-1300) there is an entry of *5l.*, paid to William de Gretham, a monk of Durham, for his expenses in carrying it from the 3rd of July to the 24th of August, and for replacing it in the church of Durham. The fame of the banner of St. Cuthbert in securing the victory was so great, that when Wilfrid Holme, an early English writer of verse, who has left a metrical account of the insurrection in the reign of Henry VIII., called the 'Pilgrimage of Grace,' speaks of various religious works or relics to which particular virtues were ascribed, he says of St. Cuthbert's banner that it "caused the foes to flee." When the Earl of Surrey commanded an expedition into Scotland early in the reign of Henry VIII., he stopped at Durham, and when he had attended mass he agreed with the prior for St. Cuthbert's banner. This is mentioned by Hall the chronicler; Skelton the poet also alludes to the fact, and names also the banner of St. William, another northern saint, as being carried in the same army.

This banner of St. Cuthbert, after the Reformation, fell into the hands of Whittingham, who was made dean of Durham, one of the zealots of the Reformation. His wife, who was a French woman, is reported to have burnt it. ('Rites and Monuments,' &c. p. 44.)

It is not our intention to introduce in this article much respecting the use of banners in other countries; but we must remark that the *oriflamme*, of which there is frequent notice in the romances of chivalry and the authentic chronicles of the middle ages, was no other than the banner of St. Denis, which, like this of St. Cuthbert, was borrowed from the abbey of St. Denis near Paris, and carried in the French armies for the encouragement of the soldiery. The oriflamme was flame-coloured, without any embroidery; below, it was divided into three parts, and it was fastened to the lance by loops of green silk. When Louis le Gros had to defend France against the Emperor Henry V., he received this banner at the altar of St. Denis with much ceremony. It was carried in the armies of St. Louis and Philip le Bel. Charles VII. had it not, the abbey of St. Denis being then in possession of the English.

Among the Saxon kings of England there were two who were reputed saints, Edmund the Martyr and Edward the Confessor. The banners of these saints accompanied the English army, and waved over the fields where our Edwards and Henries gained their victories. The device on the banner of St. Edmund was two-fold: it had a representation of Eve in the garden, and the serpent tempting her; it had also the three crowns, which were interpreted of Royalty, of Continence, and of Martyrdom. This we learn from Lydgate, a monk of Bury, where was the monastery especially founded in honour of Edmund, king and saint. The device upon the banner of St. Edward the Confessor was, no doubt, the cross and martlets as they appear carved in stone in the abbey of Westminster, where he is buried. Henry V. had also with him a banner of the Trinity, and another of the Virgin.

We probably should not err widely if we were to assert of the banners in the Middle Ages, that they formed a link between the military and the ecclesiastics, between the affairs of war and the sentiments and feelings of religion. Their influence would be felt on many occasions, but more particularly when Christians were engaged in war with the Saracens and other enemies of the faith: it was then the cross or the crescent. We may trace, even to these times, a connection between military affairs and the religious sentiment, through the medium of the banners carried in the army. Even in Protestant countries they are frequently blessed by a minister of religion. The Pope still sends consecrated banners where he wishes success. The banners of Knights of the Garter are suspended in the Chapel of St. George at Windsor, and those of Knights of the Bath in Henry VII.'s Chapel at Westminster. The churches are still the depositories of banners taken from the enemy, and banners hang over the tombs of military or naval men of distinction.

That which is peculiarly the national banner of England is a religious one. It was the practice of Christian nations, as well as of private persons, to place themselves under the peculiar tutelage of some one saint. England's patron saint was St. George, for what reason the antiquaries are puzzled to determine. But 'St. George for England' was a usual war-cry, and his banner was, above all, the banner of Englishmen. The device was a plain red cross on a white ground. Whatever other banners were carried, this was always foremost in the field; and to this day the red cross forms the most conspicuous feature in the figure which the banner of England presents.

The other parts of the figure on the national banner are composed out of the crosses of St. Andrew and St. Patrick, the patrons of Scotland and of Ireland. Both these are what the heralds call saltier-crosses, that is, crosses with the limbs extended towards the corners instead of the sides of the shield. St. Andrew's cross was white upon a blue ground. Soon after King James VI. became king of England, he directed that this cross should be united with the cross of Saint George in the national ensign. This formed what was called the Union-Flag. To this, on the union with Ireland in 1800, the cross of Saint Patrick was added. This was red upon a white ground. This did not unite with the other two so well as the cross of Saint Andrew had united with that of St. George.

The Lions of England are the personal achievement of our kings. There is reason to believe that from the time of Richard I., beyond whose reign they can hardly be traced, there was a banner, bearing the lions, always carried near the person of the king when he was engaged in war. It seems, also, that other devices which were favourite cognisances of kings of England were depicted in banners as well as carved upon the buildings erected by them, or placed in the windows. Thus, Edward IV. had a banner with the white rose of the House of York. Henry VII., after the battle of Bosworth, offered in the church of Saint Paul, at London, three banners, one of Saint George, one which had a dun cow for its device, and the third exhibiting a red fiery dragon, an ensign which had reference to his descent from the princes of Wales.

In thus carrying their own personal banners into the field, the king was imitated by the earls and other persons of distinction who were in the English armies. In the feudal times, the armies were composed for the most part of bodies of men brought up by the great tenants-in-chief of the crown, and led by that chief himself, who was bound to personal service, as well as to furnish a certain quota of men. [Army.] These persons brought banners of their own, on which were depicted the heraldic insignia of their houses. This was no doubt an affair gratifying to the passion for distinction; but it was a matter of prudence, if not of necessity, also. Heraldry was in those days, far more than at present, a necessary art,—a dumb language. When the figure was so completely cased in steel, and the face covered by the face-plate, there was scarcely the possibility of distinguishing one knight from another of the same height and general appearance. But the escallop-shells showed who were Dacres; the water-budgets, Rooses; the chevrons, Clares; and the white lion on the red field, Mowbrays, with as much certainty as if the very names themselves were painted on the shields, embroidered on the surcoats, or displayed upon the banners. The young Earl of Gloucester, grandson of King Edward I., was slain in Scotland by persons who would gladly have saved his life had they known who he was; but, as the chronicler who relates the fact observes, he had not his armorial insignia with him.

The consequence of all this was, that besides the national banner, the banner of the king, and the banners brought by men of religion, there were in the English army, in the times of chivalry, a great number of lesser banners, by which particular portions of the army were distinguished, and which served to show, as we should now say, the position in the field of the company to which each soldier belonged. This must have added greatly to the picturesque appearance of an army, which has not escaped painters and poets. References to this custom are numerous in the writers who in any way touch upon the military transactions of the Middle Ages. When, in the reign of King Richard II., there was a question in the court of chivalry, contested very tenaciously and at an immense expense, between Sir Richard Scrope and Sir Robert Grosvenor, respecting the right to the heraldic figure of a golden bend upon an azure field, the depositions in which suit have been published from the original roll in the Tower, the evidence on both sides consisted very much of the testimony of persons who said that they had seen the ancestors of one or other of the claimants exhibiting in fields of war on their shields or banners the figure in question, or had heard of it from their fathers. In the present day there is reference to the practice, when a family asserts a right to coat-armour, independently of any grant from any Earl Marshal of England. The plea is, that an ancestor bore it in a field of war, which is held to be a good and sufficient plea; and it only remains to prove a male descent from such ancestor. But the most complete exhibition of this interesting custom of our ancestors is presented in a French poem of the reign of King Edward I., relating to the siege of the castle of Carlaverock in the wars of that prince. Besides the particulars of the siege, there is given a catalogue of the chiefs who were present, which may rival in extent and minuteness the catalogue of the chiefs who went to the siege of Troy. The author touches slightly on the character of each; but he gives in good technical terms a description of the heraldic device which each displayed on his banner. A short extract will show the way in which he proceeds:—

"He had for a companion a jollie and smart bachelor, well versed in love and arms, named John Paignel, who bore on a green banner a maunch painted, of fine gold.

"The good Edmund Deincourt not being able to attend himself, sent his two brave sons in his stead, with his banner of arms billetted of gold and surcharged with a dancette.

"John le Fitz Marmaduc, esteemed by princes and dukes, and all other persons acquainted with him: on his banner was the resemblance of a fess and three popinjays, distinguished by white and red.

"And Maurice de Berkelee, who was present at this expedition, had a banner red as blood, with crosslets and a white chevron, with a label of azure, because his father was living.

"But Alexander de Bailleol, ever attentive to do good, had a white banner and shield, with a red shield voided."

Thus the poet and herald goes through the entire host, presenting us with a view, nearly complete, of the whole chivalry of England as it stood in the reign of King Edward I.

When the English army ceased to be made up of contributions from the feudal tenants, the private banner would disappear, and only the national, the regal, or the religious banner be unfurled. But in the army of the Parliament the private banner again made its appearance. Sometimes it was decorated, as in earlier periods, with the armorial insignia of the captain who displayed it; but in general the devices partook more of the character of the impresses which had come into fashion in the reign of Elizabeth, by which some moral sentiment was sought to be expressed. Thus Captain Thomas Saint Nicholas, of Kent, had a scroll on which was written, 'Dabitur victoria Sanctis.' Captain Copley displayed a banner, on which was wrought the figure of an armed knight on a bay charger, with the words, 'Nay! but as a Captain of the Lord of Hosts am I come!' A contemporary has left an account of these banners: it is a curious picture of the spirit of the times. It is printed in the work known by the title of 'Sir John Prestwich's Res Publica.'

Banners with inscriptions, or intelligible devices, afford so ready a means of diffusing a sentiment or feeling among a multitude, that they have been used in all popular insurrections. The five wounds, the crucifix, and other devices of the same class, were exhibited on banners in the insurrections in favour of the Old Religion. And in indictments for treasons in the Middle Ages, there is scarcely one which does not enumerate among the overt acts, that the party had marched with banners displayed.

The early sovereigns of England are represented on their seals, the most authentic representations which we have of them, as knights on horseback bearing little banners. But it appears, by the illuminations of early manuscripts, that distinguished persons were attended by one who carried his banner; and this was, no doubt, from the beginning the usual practice. In later times it was certainly so. In 1361, King Edward III. granted two hundred marks annual fee to Sir Guy de Bryan, as a reward for having borne his banner discreetly at the siege of Calais. Lord Boteler, of Sudeley, in the reign of Henry VI., had a grant of one hundred pounds annual fee, as due to his office of bannerer. This was probable the same office with that which was called the Standard-Bearer of England, which was held in the reign of King Henry VIII. by Sir Anthony Browne, Knight of the Garter and Master of the Horse. Inferior persons who were allowed to bear a banner in the field had also their banner-bearers.

The standard which was in use in the 11th and 12th centuries was too large to be wielded by any one hand. The French antiquaries have traced it to Italy, and describe it thus:—The drapery floated from near the top of a mast or tall tree, which was fixed in a scaffold resting on a car drawn by oxen. The oxen were covered with housings of skin, adorned with devices and cyphers of the reigning prince. At the foot of the tree a priest celebrated mass every day; while ten knights, attended by as many trumpets, kept watch upon the scaffold night and day. Such an inconvenient machine was in use in the English armies; and at the battle in the reign of Stephen, called the Battle of the Standard, one of this kind was in the field. The pole was the mast of a vessel, and it was decorated with various religious symbols, and with the banners of Saint Peter, Saint John of Beverley, and Saint Wilfred.

The chief use of the standard and of other banners in military affairs must in all times have been to serve as a rallying point to soldiers of whatever class who composed the army. But they constituted, in the middle ages, as now, the telegraphic language of war. A banner hung out from a besieged fortress was as much a sign that a parley was desired in the reign of King Edward I. as now. When a fortress was taken, the banners of England were placed in some conspicuous part of it. Vessels at sea displayed then, as now, the national or royal banner, and sometimes the banner of its commander. A herald, when sent on an embassy, carried a banner of the prince whom he served; and the drapery of a trumpet was in early times, as now, the pennon-quarrée of a banner.

In all pageants, banners have aided the splendour of the scene: at tournaments, at coronations, or funerals, banners were exhibited in great profusion.

Corporations also had their banners, and the several trading companies, who still keep them. The author of 'The Rites and Ceremonies of the Church at Durham' says that, on Corpus Christi Day, "the bailiff of the town did stand in the tolbooth, and did call all the occupations that were inhabitant within the town, every occupation in its degree, to bring forth their banners, with all their lights appertaining to their several banners, and to repair to the Abbey Church door. Every banner did stand a-row in its degree from the Abbey Church door to Windisholl-gate; on the west side of the way did all the banners stand, and on the east side of the way all the torches stood pertaining to the said banners" (p. 162). The further use of them on that day is described by Naogeorgus:

> "In villages, the husbandmen about their corn do ride,
> With many crosses, banners, and Sir John, their priest, beside;
> Who, in a bag about his neck doth bear the blessed bread,
> And often times he down alights, and Gospel loud doth read.
> This surely keeps the corn from wind and rain, and from the blast,
> Such faith the Pope hath taught, and yet the Papists hold it fast."

When the drapery of the banner was allowed to float in the air, it was usually either square or extended out to a considerable length, and divided at the extremity, so as to form what is called the swallow-tailed banner. The banner of William Rufus was of this form; that of his father has the appearance of being three shreds, each attached singly to the pole.

We refer, for other particulars, to Sir Samuel Meyrick's work on 'Ancient Armour;' and to the 'Roll of Carlaverock,' translated and published with many useful notes by Sir Harris Nicolas, which, better than any other single piece, illustrates this subject of banners.

BANNERET, a name of dignity, now nearly if not entirely extinct. It denoted a degree which was above that expressed by the word *miles* or *knight*, and below that expressed by the word *baro* or *baron*. Milles, speaking of English dignities, says that the banneret was the last among the greatest, and the first of the second rank. Edmondson ('Body of Heraldry') says the order was instituted in 736, but gives no authority; it is more generally believed to have been first created in England by Edward I. Many writs of the early kings of England run to the earls, barons, bannerets, and knights. When the order of baronet was instituted, an order with which we must be careful not to confound the banneret, precedence was given to the baronet above all bannerets, except those who were made in the field, under the banner, the king being present.

This clause in the baronet's patent brings before us one mode in which the banneret was created. He was a knight so created in the field, and it is believed that this honour was conferred usually as a reward for some particular service. Thus, in the fifteenth of King Edward III., John de Copeland was made a banneret for his service in taking David Bruce, King of Scotland, at the battle of Durham. John Chandos, a name which continually occurs in the history of the wars of the Black Prince, and who performed many signal acts of valour, was created a banneret by the Black Prince and Don Pedro of Castile. It is in the reign of Edward III. that we hear most of the dignity of banneret. Reginald de Cobham and William de la Pole were by him created bannerets. In this last instance the creation was not in the field, nor for military services, for De la Pole was a merchant of Hull, and his services consisted in supplying the king with money for his continental expeditions. We have therefore here an instance of a second mode by which a banneret might be created, that is, by patent-grant from the king. Milles mentions a third mode, which prevailed also on the continent. When the king intended to create a banneret, the person about to receive the dignity presented the sovereign with a swallow-tailed banner rolled round the staff; the king unrolled it, and, cutting off the ends, delivered it a *bannière quarrée* to the new banneret, who was thenceforth entitled to use the banner of higher dignity. Sometimes the grant of the dignity was followed by the grant of means by which to support it. This was the case with some of those above-mentioned. De la Pole received a munificent gift; the manor of Burstwick, in Holderness, and 500 marks, annual fee, issuing out of the port of Hull. (Dugdale's 'Baronage,' vol. ii.)

The rank of the banneret is well understood, but what particular privilege he enjoyed above other knights is not now known, beyond being allowed to bear arms with supporters. It was a personal honour in England, though in France it was hereditary; and yet in De la Pole's patent it is expressed that the grant was made to him to enable him and his heirs the better to support his dignity. But the patent was perhaps irregular, as it seems to have been surrendered. No catalogue has been formed of persons admitted into this order, and it is presumed that they were few. The institution of the order of baronets probably contributed greatly to the abolition of the banneret. The knights of the Order of the Bath in modern times approach nearest to the bannerets of former days. In the civil wars, Captain John Smith, who rescued the king's standard at the battle of Edgehill, was created a banneret, and he was the last; he was killed in the skirmish at Alresford, in Hampshire.

It remains to be observed that the French antiquaries since Pasquier have represented the banneret as having been so called as being a knight entitled to bear a banner in the field; or, in other words, a knight whose quota of men to be furnished to the king's army for the lands he held of him were of that number (it is uncertain what) which constituted of itself a body of men sufficient to have their own leader. In England it is believed there were few tenants bringing any considerable number of men who were not of the rank of the *barones*.

BANQUETTE is a term applied in fortification to the step or small terrace of earth, made on the rampart, and against the parapet of a work, to enable the defenders to fire over its crest. The upper surface or *tread* of the banquette, which is generally about 4 feet wide, should be within 4 feet 3 inches of the crest of the parapet, in order that the men may conveniently use their muskets over it. The tread is reached from the terreplin of the rampart, or from the ground, if it is only a field work, by steps; or by the earth being sloped to the rear with a slope of 1 in 2, which men can easily run up, and having discharged their pieces, retire down again under cover. In the defence of houses, barricades, &c., the banquette is made up of tables, chairs, or anything which will raise the defenders to a sufficient height to fire through the loop-holes.

BANS. [BAN; MARRIAGE.]

BAPTISM (the English form of the Greek word βαπτισμὸς, *baptismos*), a well known rite or ordinance of Christianity; one of the two sacraments of the English Reformed Church.

When baptism, as a religious rite, was first practised, is a question on which the opinions of the learned have been divided. It is pretty generally admitted, that if any trace of it is to be discovered in the religious usages of any people before the time of our Saviour, and his forerunner John, it is among the Jews; and some early Jewish writers, whose testimony on such a subject is worthy of some regard, speak of it as a custom of their nation from very ancient times, and as having been always an accompaniment of circumcision, whether of infants or when a proselyte was made. To this it is replied, that the Hebrew writings which are called the Old Testament, by far the most ancient and authoritative monuments which we possess of the early religious usages of that nation, contain no trace whatever of any rite which resembles the baptism of John and of the founder of Christianity. In their religious code ablutions are undoubtedly prescribed in certain cases, but there is no analogy between those cases and the cases in which the Christian rite of baptism is performed; yet it is by no means improbable that those ablutions, which were supposed to wash away impurities, might suggest the idea of baptism, with which has always been connected, in some degree, the notion of the washing away of moral impurity.

We possess, however, the most authentic and satisfactory information, that in the reign of Tiberius there appeared in the wild country, on the banks of the river Jordan, a prophet whose name was John, who called upon the people of Judæa to adopt stricter rules of life, to expect the immediate coming of the kingdom of heaven, and to repent. Great multitudes attended the preaching of John. Most of those who heard him received him as a prophet sent of God. He required of those who became his disciples that they should be *baptised*. This was done in the river, and the meaning of the rite seems, in this case, to have been two-fold: 1. Repentance, or renouncing former opinions and practices; and, 2. Proselytism, or the taking John to be their general spiritual or religious guide and authority. On account of his requiring his proselytes to submit to this rite, the name of the Baptist was given him.

The part which John sustains in the history of Christianity is subordinate to that of a more sacred character, and we hear little afterwards of any sect, or community, or church, held together by a common reverence for the name of John, and the individuals of it baptised into that name. Among those who acknowledged John as a divine prophet, and received baptism at his hand, was Jesus of Nazareth, the long-expected Messiah, at whose baptism there was a supernatural appearance in the air, and a voice heard, which declared him to be the "beloved Son of God, in whom he was well pleased." John also bore his testimony that Jesus was the Messiah. Jesus founded that great church or community in which so large a portion of the human race are now comprehended, and appointed that admission into this church should be accompanied by the rite of baptism.

It is remarkable that he did not himself baptise. But while he was himself employed in diffusing that new and sacred truth which he came to communicate, and in the performance of those miracles by which his claim to be a divine teacher was established, his apostles and others of his more eminent disciples did baptise, and many flocked to their baptism. (John iv. 1, 2.) This was done under the eye and with the concurrence of their master, but after his resurrection he gave a more direct sanction to the practice, and in fact established the rite as a perpetual ordinance in his religion, saying to his apostles—"Go ye therefore and teach all nations, baptising them in the name of the Father, and of the Son, and of the Holy Ghost, teaching them to observe all things whatsoever I have commanded you." (Matt. xxviii. 19, 20.)

The apostles acted according to this injunction. The language of Peter on the day of Pentecost to the Jews at Jerusalem was this:—"Repent and be baptised every one of you in the name of Jesus Christ for the remission of sins:" when they that gladly received his word were baptised, to the number of three thousand. (Acts ii. 38, 41.) In the eighth chapter of the Acts we have an account of two remarkable baptisms by Philip; and in the same book are so many accounts of the performance of this rite when there was a profession made of belief in Christ, and there are at the same time so many allusions to the practice in the apostolic epistles, that there is no room for doubt that it was regarded by the apostles and first Christians as an instituted ordinance of the Christian church. The meaning of Christian baptism differed little, if at all, from the baptism of John. It implied repentance and faith in Christ.

The washing was no inapt symbol of this change. When formally administered by some officer of the Christian Church, and in the presence of a Christian assembly, it was an outward and visible sign that the convert took upon himself the profession of Christianity. It was an intelligible act about which there could afterwards be no dispute. The convert might relapse; but if he had once been baptised, there was once a time when he had professed himself a Christian, and when he had given a solemn pledge that he put away his Heathen or Jewish opinions and practices, and adopted the principles of the Christian faith. On the other hand, the performance of the rite by an apostle, or by a person commissioned by the apostles, or by any other person who was himself a Christian, and who professed that he was performing the rite as a Christian ordinance, and in obedience to the command of Christ, was an assurance to the person baptised that he was received into the Christian Church, that he was henceforth to be acknowledged by the whole Christian community as one of themselves, and was become entitled to all the blessings and advantages which attend those who are disciples of Jesus Christ. Our parish registers are not of births but of baptisms, and they are the authoritative records of the admission, by this rite, of persons into the Christian Church; the registry by the registrar is altogether independent of the baptism.

Different opinions are entertained of the amount of the advantages which ensue on the performance of this rite. Some regard it as not of itself bringing with it any advantages, but as being merely initiatory, and consider that the advantages of a profession of Christianity spring from other sources within the profession itself. Some regard it as in itself an actual washing away of all former sins, and, in the case of infants, of their participation in the guilt of Adam; and under this impression, we find that, in the early ages of the Church, there were those who deferred submitting to the rite till near the close of their lives, that the guilt of a whole life might thus be washed away. Others have taken their stand on the declaration of the apostle (Acts ii. 38), that those who were baptised should receive the gift of the Holy Ghost, and imagine that there is now some effusion of the Spirit on the person baptised. Some attribute to this rite what is called an immortalising efficacy, so that by baptism alone a person becomes entitled to that immortality which Jesus of Nazareth revealed; and others, again, regard baptism and regeneration as correlative. These opinions have all given occasion to controversies in the Church.

The manner in which it was performed appears to have been at first by complete immersion, "as a sign of total baptism into the Holy Spirit, being entirely penetrated by his grace," says Neander; who adds, that it was only in cases of sickness that sprinkling was allowed. ('Hist. of the Christ. Rel.,' sect. ix.) John baptised in the Jordan; and in another place (John iii. 23) it is said that he baptised "in Ænon, near to Salim, because there was much water there." The Ethiopian eunuch went down into the water to receive baptism from Philip. The words *baptism*, and to *baptise*, are Greek terms, which imply, in their ordinary acceptation, *washing*, or *dipping*. The question, however, is not whether entire immersion were the practice in the primitive church, but whether it was regarded as so essentially a part of the ordinance that there could be no baptism without it; and against that opinion it is argued, that this is nowhere declared in the Christian Scriptures; that a partial washing is, as a symbol, or an initiatory rite, as efficient as an entire immersion; that there is no evidence that entire immersion was in all cases demanded by the apostles; that we can hardly conceive that the three thousand converts who were baptised on the day of Pentecost received the rite at Jerusalem by immersion; that in one of the most remarkable cases of baptism recorded in the New Testament (Acts xvi. 33), the jailer and his family were baptised by St. Paul in the night immediately after they had made the profession of their faith, when it is improbable that the means were at hand for entire immersion; and that it is not to be supposed that the apostles would have declined to communicate the advantages of Christianity where they perceived faith and repentance, though the party were in circumstances in which it was impossible, or at least extremely inconvenient, to perform the rite in the usual manner; whence it is inferred that entire immersion is not *essential* to the ordinance.

The words which are to be used in the performance of this rite are thought, by most persons, to be prescribed by Jesus Christ himself;—"Baptising them in the name of the Father, and of the Son, and of the Holy Ghost." These words have been adopted as the formula by, it is believed, every church; yet it is remarkable that we do not find these words to have been used as a baptismal formula in any of the baptisms of which we have an account in the book of Acts; and in the account of some of them it is expressly said that the parties were baptised in the name of Jesus. (Acts ii. 38, and xix. 5.) It would seem, from the manner in which St. Paul writes to the Corinthians (1 Ep. i. 11-17), as if there were at that time some danger lest eminent Christians should be ambitious of having baptisms in their own names.

The opinions of the Christian world have been much divided with respect to the time of life at which it is proper to administer the ordinance. At first it was administered only to adults; it marked the reception of a new faith. When Christianity addresses herself to the unconverted, the proper time evidently is whenever the faith and repentance necessary are perceived to be complete; but the question relates to the case of nations which are already Christianised, and it properly assumes this form:—Shall the performance of the rite be delayed till the offspring of Christian parents are sufficiently advanced in religious knowledge to have the faith, and, if need be, the repentance of the convert? or shall those who are born in Christian households, and for whom there is the serious intention entertained by those who are their natural protectors to bring them up in the faith and knowledge of the Christian, be devoted early by their protectors to the faith of Christ, and admitted, in their still unconscious state, to whatever advantages may be supposed to attend the performance of this rite? Without entering at large into the controversy which was raised on this point, as early as the close of the 2nd century, by Tertullian, we may observe that, on the one hand, any profession of faith or repentance can only be made by persons of some maturity of judgment, and that therefore the ordinance seems better adapted to the case of persons who have attained to those years in which it may be expected that there is some acquaintance with the evidence by which the divine commission of our Saviour is proved, some knowledge of the nature of the doctrine taught by him, and some real sense of the advantages which attend the true believers in Christ. On the other hand, it is alleged that there is nothing in the New Testament which relates to the baptism of the offspring of parents themselves Christian, but only to the baptism of converted persons, leaving us without an authoritative direction in the case; that it was natural for the first converts, who were Jews, to infer an analogy between this rite and the initiatory rite of Judaism, which, by the divine command, was to be performed in infancy, and which brought the person who received it within the scope of the promises to Abraham and his seed, as baptism did within the scope of the promises to believers in Christ; that we read in the Scriptures of whole households being baptised at once (Acts xvi. 15, 33); that infant baptism certainly did prevail in the Church at a very early period; that it has been received by the authorities in the Roman Church, and in the Churches of England and of Scotland, and other Protestant Churches; and, lastly, that among those who attribute a saving efficacy in any form to the ordinance, it is to be supposed that a parent would think himself criminal if he neglected to obtain this blessing for his child at the earliest period possible, as St. Paul, in 1 Cor. vii. 14, says, "else were your children unclean, but now are they holy;" and even among those who regard it as but initiatory, that there is a propriety in Christian parents presenting their offspring newly-born in a Christian temple, and pledging themselves to a Christian minister, and in the presence of a Christian congregation, that they will bring it up in the knowledge and fear of God through faith in Jesus Christ.

The Quakers and some other Christians contend against the perpetuity of the ordinance. They say that it was intended only for the apostolic age, or, at most, only for persons of mature age who have been converted from heathenism or Judaism. Against this opinion there is the constant practice of the Church. We find, at the very close of the Scripture history, the apostles and other Christians proceeding with their baptisms; and at the very beginning of that history of the affairs of the Church which is to be collected from writers whose works are not in the New Testament, we find the ordinance in use among believers. The inference drawn from this is, that the words of our Lord, by which he instituted the ordinance, were understood by his apostles to mean, that all persons should be admitted into his Church by this rite, and that they transmitted this sense of them to those who afterwards were the teachers in the Church.

When baptism was received as a permanent ordinance of the Christian Church, suitable places were provided, called baptisteries, which, in some instances, preceded churches, and were, in fact, the point about which other edifices arose, forming an entire church. [BAPTISTERY.] In many of the larger churches of England, a portion of the building is set apart for the performance of this rite, and contains the *font*, so called from *fons*, a fountain, perhaps in reference to the original baptisteries, the springs or running streams of the East, or as the Spring of that water which was supposed to be life-giving. The maintenance of a font in the church for baptism is enjoined on every parish. Many of the old fonts of England have capacious basins, large enough to receive the entire body of the infant. It was the practice of the English Church, from the beginning, to immerse the whole body. (See Fuller's 'Church History,' p. 109.) Tyndale, writing at the eve of the Reformation, speaks of it as the general practice, and says that the exceptions were in cases of sickness, when the water was only poured on the head of the infant. Dr. John Jones writing in 1579 on the early culture of children, incidentally notices the fact that some of the old priests of that time were accustomed to dip the child very zealously to the bottom of the font. A few years later the practice was giving way, and the custom of sprinkling only becoming general; for Chappell, Bishop of Cork, in the account which he has left of himself, says that he was dipped, as was the custom of the parish in which he was born. He was born in Nottinghamshire, in the reign of Elizabeth. Since then the baptism of infants by immersion has been almost entirely disused in England. [FONT.]

At the Reformation it was intended to continue an ancient practice in the baptism of infants—the trine immersion; and there was an ordinance for the purpose in the reign of Edward VI. This has reference to the three persons in the Godhead named in administering the rite; and when performed according to what is supposed to be the genuine ancient usage, at the first immersion the right side must be downward, at the second the left, and at the third the face. Instances do sometimes occur in which the baptism of infants in the English Church is thus performed.

It has always been an object with the authorities in the Church of England to enforce the attendance at the public font in the Church. Private baptism is rather connived at than allowed, except in cases in which there is sickness or hazard of life; nor is the clergyman in these cases to perform the full service, but only so much as may be needful, in the estimation of himself and the parents, for satisfaction that the child, if it dies, die not unbaptised. The friends of the infant must still repair to the church for the completion of the ceremony. Among Dissenters, the baptism of infants has been, for the most part, peformed at home.

It is not absolutely necessary that the rite should be performed by a clergyman. The Church of England allows, in certain cases, of lay baptism; and it was on this allowance, in a great measure, that Sir John Nicholl rested the case in his judgment pronounced on the 11th of December 1809, in the case of Kemp and Wickes, clerk. Articles were offered against the clergyman for refusing to inter the child of two of his parishioners on the ground that it had not been baptised. It was proved that it had been baptised by a Dissenting minister. Sir John Nicholl's judgment was, that the baptism was so far sufficient, and that the clergyman had acted contrary to the law.

The Church requires that at baptism there shall be *sponsors*, from *spondeo*, to promise, or, in our own Saxon tongue, *godfathers* and *godmothers*, who pledge themselves that the infant shall be brought up in a Christian way. They are to be not less than three: for a male child, two men and one woman; for a female child, two women and one man. This practice is of great antiquity in the Church. It probably was adopted correlatively with infant baptism, as the infant could not of itself make the necessary profession of faith, and which was therefore promised for him; and Tertullian uses this as an argument against infant baptism, because the obligation undertaken by the sponsors was one that many circumstances might prevent their fulfilling. The practice however remains, and its effect is to introduce one other social tie among private families and friends. Persons who voluntarily undertake the office cannot hold themselves absolutely excused from some attention to the religious education of the infant, especially in the case of the death, or the criminal negligence, of its natural protectors.

Another incident to baptism, as administered in the English Church, is the giving a name to the child. If the child is registered before baptism, a name must be given, and this name must be retained, but additional names may be bestowed at the time of baptism. In this Christians seem to have followed the example of the Jews, who assigned a name when the rite of circumcision was performed. The name thus given during the performance of one of the sacraments is appropriately called the Christian name. The surname, or name of addition, is not on this occasion mentioned; and it is observable, that though there are frequent instances of the change of the surname in after life, the instances are extremely rare of any change in the Christian name. In the Roman Catholic Church indeed this name is not unfrequently changed by persons who enter holy orders, or into any religious society; but the English Protestant Church seems not to have pointed out the way in which the change can be legally effected, though some have maintained that it may be changed by the authority of the bishop, if solicited by the party at the time when presenting himself for confirmation.

The Church of England retains the signing the infant with the sign of the cross, as a token that it is hoped it will become a good soldier of Jesus Christ. This is one of the ceremonies which the English reformers thought it expedient to retain from many ceremonies with which this ordinance had been loaded in the earlier times of the Church. These additions to the simplicity of the ordinance began at a very early period. Tertullian, a Christian writer, who flourished from about A.D. 194 to 216, says that it was then the custom to give the baptised person milk and honey, and that he abstained from washing for the remainder of the day. The giving of salt, the touching the mouth and ears with saliva, anointing, the imposition of hands, and, lastly, formal exorcism, were by degrees introduced into the ordinance; and most, if not all, of them were the practice of the English unreformed Church. The sign of the cross was alone retained; but this gave great offence to the party of reformers called Puritans, who would have brought back everything in respect of religion to what they conceived to be the precedent, or the express directions of Scripture.

The most important treatises on the subject of baptism are: 'The History of Infant Baptism,' by William Wall, D.D., 1705; 'Reflections on Mr. Wall's History of Infant Baptism,' by John Gale, D.D., 1711; 'History of Baptism,' by Robert Robinson, 1790; 'The Nature and Design of Christian Baptism,' by R. A. Lancaster, 1855.

BAPTISTERY, a building in which the early Christians performed the ceremony of baptism. The word is derived from the Greek *βαπτιστήριον*, a large vase, labrum, or piscina of the frigidarium used to wash in. [BATH.] (Plin. lib. 2, ep. 17; lib. 5, ep. 6.) It was called by the Romans *baptisterium*, from whence is derived the word baptistery, a place in which the ceremony of Christian baptism was performed. It is most probable that the early Christians baptised for a long time after the primitive manner which was practised by St. John (Mat. iii.

6, 16). Baptisteries were afterwards erected on a large scale, for the purpose of receiving a great number of individuals.

These baptisteries were originally in most cases placed at the west end of the basilicas to which they belonged; but afterwards were attached to or included in the churches. The form is, for the most part, hexagonal or circular; and it is very probable that the form of these buildings was imitated from some apartment in a Roman bath. [See BATH; and the plan of a Roman bath discovered at Bologna, cap. vi. of Cameron's 'Roman Baths;' and the Church of Santa Maria Maggiore, near Nocera, formerly a Roman bath; and especially the vignette at the commencement of the same work.]

The most celebrated existing baptisteries are those of Rome, Florence, and Pisa; the most ancient is the baptistery of S. Giovanni in Fonte, near the church of S. Giovanni Laterano, at Rome, commonly said to have been erected by Constantine the Great. The plan of this building is an octagon, with a small portico at the entrance; the interior is decorated with eight beautiful porphyry columns, the finest of the kind in Rome. These columns, unequal in diameter, support an architrave, over which eight small white marble columns are placed; above this second order there is an attic decorated with pilasters, and this is crowned with a dome. The walls are adorned with frescos, consisting of subjects from the Gospel and the principal events of the reign of Constantine. In the centre of the building is an octangular basin, three feet deep, lined and paved with marble. A modern font now stands in the centre of this basin, raised on steps of marble. The internal diameter of this structure is about sixty-five feet; and it appears to have been constructed with the materials of other buildings. Eustace calls this structure a chapel, and informs us that in it "only, and upon the eves of Easter and Pentecost, was public baptism administered in Rome; many magnificent ceremonies, which occupied the whole night, accompanied this solemnity." (Eustace's 'Class. Tour,' vol. i. p. 337.)

The Baptistery of Florence, which is also octangular, with a diameter of about one hundred feet, according to the plan in the 'Metropolitana Fiorentina,' stands opposite to the principal entrance of the cathedral. The date of its first construction is unknown; the Florentines pretend that it was originally a temple to Mars. In the internal arrangement, sixteen large granite columns are employed to support a gallery, which is carried nearly all round the interior; the vaulting is decorated with mosaics, by Andrea Tafi, the scholar of Cimabue; on the pavement is a large circle of copper, with numerical figures and signs of the zodiac upon it; and in the centre of this was originally a very fine octagonal basin. The external façades are built of black and white marble, and designed in that peculiar style of Florentine architecture of which Giotto was the father. Possibly this edifice may have been erected after his designs. The three great bronze doors are celebrated for the beauty of their bas-reliefs, and for the marble and bronze figures above them. The valves of the doors are divided into panels, on which are represented the principal events of the life of St. John—"the cardinal and theological virtues," and subjects from the Old and New Testament; and so important was the subject considered, that Nicolo da Uzzano and Lionardo d'Arezzo were engaged to select subjects for the sculptor. The most celebrated of these doors was made by Lorenzo Ghiberti, in 1330, and in after times eulogised by Michael Angelo in the highest style of panegyric. (See thirty-four engravings of 'La Terza Porta di San Giovanni di Firenze,' Firenze, 1773, in small folio, in the British Museum.) Another was made under Ghiberti's direction, assisted by many other artificers. Fifty years were employed in making and completing them. (See the work quoted above, in which are also published the contracts for their execution.) The most ancient was made by Andrea of Pisa.

The Baptistery of Pisa, erected between the years 1152 and 1160, by Diotisalvi, is of a singular design. The plan is circular, with a diameter of 116 feet; the walls are eight feet thick; the building is raised on three steps, and surmounted with a dome in the shape of a pear. The external elevation is divided into three stories: in the basement the columns, twenty in number, are engaged, and have arches springing from column to column, with a bold cornice above; in the first story the columns are smaller, stand out in relief, and are placed closer together; and the order is surmounted with pinnacles and high pediments, placed at equal distances: the terminations of these parts are crowned with statues. Above this is an attic story, decorated with other high pediments, pinnacles, and statues. The dome, which is covered with lead, is intersected by long lines of very prominent fretwork: all the lines meet in a little cornice near the top, and terminate in another dome, above which is a statue of St. John. The interior is much admired for its proportions: eight granite columns, placed between four piers decorated with pilasters, are arranged round the basement story; above this is a second order of piers, arranged in a similar manner, on which the dome rests, which is famous for its echo, as the sides produce the well-known effect of whispering-galleries. In the plan drawn by J. and F. de Milanis, preserved in the British Museum, columns are not shown in the interior. In the middle of the baptistery is a large octagonal basin of marble, raised on three steps. Within the basin there are four circular places hollowed out for water, and round the centre of the basin, which is occupied by a pedestal, is a place likewise hollowed out for the priest, who was thus enabled to turn from one basin to the other. By this means confusion was prevented, which would otherwise have occurred from the crowd pressing to one side of the font only. The city of

Scale 0 50 100 feet.

Ravenna and the episcopal cities of Tuscany have also their baptisteries. There are some interesting baptisteries in Germany; in France and England remains of baptisteries are rare and seldom of much importance.

The largest known baptistery ever erected was that belonging to the church of Santa Sophia at Constantinople, which is said to have been so spacious as to have once served for the habitation of the Emperor Basilicus; and in it also a very numerous body of persons once assembled in council.

The multangular edifices placed at the sides of cathedrals, which are called chapter-houses, are very similar in plan to the ancient baptistery. It is possible that they were originally used for that purpose. Bede mentions a wooden *oratory* built in haste at York for the express purpose of baptising Edwin, king of Northumberland, on Easter-day, A.D. 627. (Bentham's 'History and Antiquities of the Conventual Church and Cathedral at Ely.') The baptismal font [FONT] is not synonymous with baptistery; but should be applied only to the large stone vessel placed in the centre of the baptistery. At the close of the 6th century, the baptismal fonts belonging to baptisteries began to be placed in churches. At a font placed in a church the French King Clovis received baptism at the hands of St. Remis, archbishop of Rheims.

The baths in the English Baptist meeting-houses which are used for baptism are called baptisteries. They are not invariably *in* the places of worship.

(Montfaucon's *Monumens François*, vol. i.; Eustace's *Classical Tour; Ristretto delle Cose le più notabili di Firenze, &c.;* Cameron's *Roman Baths; La Metropolitana Fiorentina; La Terza Porta di S. Giovanni di Firenze,* small folio; Nolli's *Plan of Rome;* and the *Plan and Elevation of the Baptistery at Pisa,* by J. and F. de Milanis: the two last are in the King's Library in the British Museum. Plans, sections, and elevations of this building are given in Messrs. Taylor and Cressy's *Architecture of the Middle Ages in Italy.*)

BAPTISTS, a religious sect, and, in England, one part of the body known by the general name of the Three Denominations of Protestant Dissenters. As the name implies, they hold peculiar views on the subject of baptism, maintaining that this Christian rite ought to be administered by immersion, and not by sprinkling, at such an age that the ordinance can be regarded as the profession of the baptised person's own faith, and not in infancy. Such, they believe, was the practice of the apostolic times. In vindication of their mode of performing the ordinance, they lay great stress on the original word βαπτίζω which signifies, as they contend, nothing but immersion.

They defend the postponement of the rite from the words of the baptismal commission, in which the Apostles are commanded to teach before they baptise: "Go ye and teach all nations, baptising them in the name of the Father, and of the Son, and of the Holy Spirit." The reception of the Gospel being thus assumed as an indispensable qualification for baptism, the Baptists require that all to whom they administer it should repent of their sins, believe in Christ, and joyfully receive the word; a profession to this effect is made by most persons who are baptised in their communion.

An outline of the characteristic opinions of this sect has been promulgated in the four following heads:—1. That baptism commenced with the Christian dispensation, and was peculiar to it, bearing no analogy to any previous institution, such as circumcision; nor in any sense derived from previous enactments, but revealed as a positive law of the kingdom of Christ. 2. That baptism is only scriptural as administered by the immersion of the whole body in water. 3. That it cannot scripturally be administered to any but as a profession of faith in Christ Jesus, and therefore not to infants. 4. That as a command of the New Testament, it is obligatory on all who profess faith in Christ, and is intended to form a great line of separation between Christ and the world.

The question of baptism was brought before different councils in the 5th century, whose decisions were given in favour of infant baptism. The opposite opinions were therefore anathematised, and those who held them incurred the penalties attached to heresy. The baptismal controversy is alluded to in the writings of several of the fathers, some of whom did not scruple, in spite of edicts and decrees, to condemn the practice of baptising infants, as a deviation from Scripture and the early custom of the Church. The same view of the subject was very prevalent in the eastern provinces of the Roman empire, where it became so popular that, in the 9th century, when that powerful schism arose which led to the formation of the Greek Church, this was one of the articles in which an irreconcileable difference of opinion prevailed between the new communion and the old; the Western Church adhering to its established custom of sprinkling infants in baptism, while the Greek Church performed the ceremony by trine immersion.

The schism which had occasioned such a defection from the Church of Rome did not remove the cause of controversy concerning baptism; but, on the contrary, increased it by the intolerant proceedings which were taken against those who refused to be silenced. Driven from the bosom of their own communion, they took refuge in the churches of the Waldenses, in the vallies of Piedmont, and, at a later period, joined the disaffected sects in Germany and Flanders, amongst whom they sowed the seeds of their own doctrines. The zeal with which they laboured to spread their opinions only made them a more conspicuous mark for persecution. Imprisonment, exile, or death, was the fate of those who persisted in their adherence to this heresy. All the terrors of the Church were invoked to extinguish the offensive tenet; but so rapid was its growth under persecution, that the numbers of those who professed it in the beginning of the 12th century are said by Mosheim to have amounted to 800,000.

From this time to the commencement of the Reformation, Germany was the chief seat of the Baptist reformers; from whence, following the course of the Rhine, they spread over Holland. Being thus scattered over that part of the continent in which the doctrines of the Reformation were agitated, they availed themselves of the opportunity of gaining attention to their own views. From this great epoch in the history of religious opinions may be dated a new era in the history of baptism. Up to this time the doctrine, though so long and tenaciously maintained, appears not to have bestowed any particular designation upon those who held it. Their existence, as a distinct sect, commenced in Germany in the days of Luther, under the name of Anabaptists. Unhappily for the success of the doctrine, it was blended with principles so fanatical and lawless, that none who had a respect for the morals and order of society dared to avow it. So disreputable did the very name of this disorderly sect become, that it has made the advocates for baptismal immersion averse to the name of Anabaptists. The term Baptist has the advantage of being more etymologically correct than the earlier designation of Anabaptist, as *ana*baptism is only an accident, and not an essential circumstance. It is only necessary for us to remember, in order to preserve the thread of their history, that those persons who first insisted upon the necessity of baptismal immersion were, and are still, frequently known on the continent by the name of Anabaptists (in German Wiedertäufer), although the opinions now held by them bear a close, if not a complete, resemblance to those of their English brethren who are called Baptists. But the term Wiedertäufer is considered by the continental Baptists as a word of reproach; and in Germany they prefer to call themselves *Taufgesinnte*, and in Holland *Doopsgezinde*. The Mennonites, so called from Menno Simonis, always disclaimed all connection with the Anabaptists of Münster; they now form a numerous body in Holland, and are found in various parts of Germany; in Prussia they are said to amount to 15,000.

Little is known of the Baptists in England before the 16th century. Their name then appears among the various sects who were struggling for civil and religious freedom. Their opinions, at this early period, were sufficiently popular to attract the notice of the national establishment, as is evident from the fact that, at a convocation held in 1536, they were denounced as "detestible heresies utterly to be condemned." Proclamations followed to banish the Baptists from the kingdom; their books were burnt, and several individuals suffered at the stake. The last person who was burnt in England for his religious opinions was a Baptist, of the name of Edward Wightman, of Burton-upon-Trent: he was not, however, burnt as a Baptist, but for blasphemy and heresy.

We do not hear of any congregation of Baptists in this country before 1607. At that time one was formed by Mr. Smyth, a clergyman of the Church of England, who, having embraced the leading tenet of this denomination, resigned his living, and opened a place for public worship on the principles of the Baptists in the metropolis. This step encouraged others to follow his example who had hitherto concealed or privately professed their opinions. The forms of worship adopted by these congregations, that sprung up in various parts of England and Wales, did not materially vary from the practice of the Puritans. The reformed churches on the continent furnished a model for all the sects which then contended for the right of nonconformity, and have flourished since under the name of the Three Denominations of Protestant Dissenters. Among these, the Baptists were not the least distinguished for the consistency of their conduct in maintaining the right of private judgment, and in advocating the principle of universal toleration in matters pertaining to religion.

The Baptists subsist under two denominations, namely, General and Particular Baptists. The latter designation is given to those who hold Calvinistic views, and who are in every respect but their distinctive doctrine the same as the Independents. The General Baptists maintain the doctrine of universal redemption; but they are divided into the Old Connexion (Unitarian), and the New Connexion (Trinitarian), the latter by far the most numerous. Among both the Particular and General Baptists there is another ground of separation, relating to the terms of communion at the Lord's Supper. Some churches (each society or congregation is a church) do not allow persons who have not received baptism according to their views of it, to join with them in the celebration of this rite. Of this number are some of the Particular Baptists, and all the New Connection of General Baptists. Others, however, do not scruple to meet, on that occasion, not only those of the Baptist persuasion who hold other opinions widely different from their own, but even persons who do not embrace the Baptist tenet, provided their religious faith is, in other respects, as they conceive, orthodox, and their lives conformable to their profession. This is called Free Communion. The tolerant spirit which it cultivates, advocated as it has been by those eloquent defenders of liberty, Robert Robinson and Robert Hall, has made considerable progress through the whole denomination.

In Ireland and Scotland the Baptists have many congregations; but neither there nor in this country do their opinions spread so fast as in the United States of North America. The number of registered members in 1854, was 1,078,754. In Great Britain the census returns of 1851 gave the number of places of worship of the Particular Baptists as 1947, of the General Baptists as 93, of the New Connexion General, as 182, and 567 as those of Seventh Day, Scotch, and Baptists not otherwise designated. Sittings are provided in these places for 705,663 persons, of which 550,749 were in those of the Particulars. The total of attendants on Sunday, March 30, 1851, was 337,614, of whom 267,205 were Particular Baptists. These returns, are, however, acknowledged not to be precisely accurate, as there were 181 places which did not make returns of the number of attendants. In the United States, the "church accommodation" of the Baptists at the census of 1850 was 3,248,580, being much larger than that of any other denomination except Methodists: the number of church members was estimated at nearly a million (982,693); but these numbers include all the several descriptions of Baptists, which are more numerous in America than in England. Their church property was estimated at the sum of 10,931,382 dollars, and they then had eleven theological schools.

The Particular Baptists support colleges at Bristol, Bradford, Pontypool, Haverfordwest, and in Regent's Park, London; and the General Baptists of the New Connexion have a college at Nottingham, for the education of young men for the Baptist ministry. They have funds and associations for aged ministers, for widows, and for the education of the children of their ministers. Besides these, their pecuniary exertions for the support of home and foreign missions are very considerable. The English Baptists are among the foremost who sent Missionaries abroad to teach the doctrines of Christianity. For the advancement of this object, they have numerous agents in distant countries; in addition to which, they employ a great number in visiting the rural districts at home.

(*An Historical Sketch of the Baptist Denomination*; Mosheim's *Ecclesiastical History*, vol. iv.)

BAR is a term applied, in a court of justice, to an inclosure made with a partition of timber, three or four feet high, with the view of preventing the persons engaged in the business of the court from being incommoded by the crowd. It has been supposed to be from the circumstances of the counsel standing there to plead, that those lawyers who have been called to the bar, or admitted to plead, are termed *barristers*, and that the body collectively is denominated *the bar*; but these terms are more probably to be traced to the arrangements in the inns of court. [Barrister and Inns of Court.] Prisoners are also brought for trial to the same place; and hence the practice of speaking of them as the 'prisoners at the bar.' The term bar is similarly applied in the houses of parliament to the partition which divides from the body of the respective houses a space near the door, beyond which none but the members and clerks are admitted. To these bars witnesses and persons who have been ordered into custody for breaches of privileges are brought; and counsel stand there when pleading before the respective houses. The Commons go to the bar of the House of Lords to hear the speech of the sovereign at the opening and close of a session.

BAR, in music, a perpendicular line drawn through the staff [STAFF], dividing a piece of music into certain equal portions or measures, in order to render its execution more easy. The term *bar* is also applied to the quantity contained in any such portion: thus we say, a bar of two minims, of six quavers, &c.; and a bar in common time, in three-eight time, &c. Sir John Hawkins remarks, that the use of bars is not to be traced higher than the year 1574, and that it was considerably later before their use became general. He conjectures that we are indebted for their common use to Henry Lawes, who published his 'Dialogues,' &c., in 1653. That laborious historian may be right as relates to this country; though, with a work lying before us, 'Madrigali e Canzonette, posti in Musica dal R. P. Severo Bonini,' dated Firenze, 1607, in which the bars appear throughout, we cannot bring ourselves to think that nearly half a century elapsed before so obvious an improvement was adopted in England.

Double Bars mark a conclusion. They are likewise placed at the end of each strain; and if accompanied by dots, as in the example, they

indicate that the part next the side on which the dots appear is to be repeated.

BAR IRON. The relations which bar-iron bears to other forms of the manufactured metal will be described under IRON MANUFACTURE; but it may be useful in this place to notice the vast extent to which these products of industry are now exported. In the Board of Trade returns, bar, bolt, and rod iron are included in one return. The most important of these items is that of railway bars, with which England supplies a large portion of the world. In the three years ending with 1858, the average quantity of bar, bolt, and rod iron exported amounted to no less than 5,900,000 tons annually; of which 1,600,000 tons went to the United States, and 1,100,000 tons to the East Indies.

BARALIPTON. [SYLLOGISM.]

BA'RBACAN, or BARBICAN (*Barbacâne*, Italian; *Barbacane*, French), in ancient fortification, was usually a small round tower for the station of an advanced guard, placed just before the outward gate

Walmgate Bar and Barbacan, York. From "The History and Antiquities of the Fortifications to the City of York," by Messrs. Lockwood and Cates, architects. Lond. 1834.

of the castle-yard or ballium. (King's 'Sequel to his Obs. on Ancient Castles,' Archæol., vol. vi. p. 308.) Whence Spenser, in the 'Fairy Queen,' b. ii.,

> "Within the *barbacan* a porter sate,
> Day and night duly keeping watch and ward."

Grose ('Antiq. of England and Wales,' vol. i. pref. p. 5) calls it the first member of an ancient castle. He says it seems to have had no positive place, except that it was always an outwork. The term is still preserved in the ruins of different castles, as at Framlingham and Canterbury castles; and a small stone-work covering the gate of Bodiham Castle, in Sussex, is still called the barbacan; and barbacans also remain in tolerable preservation at Carlisle Castle, where the general arrangements of a barbacan may perhaps be better studied than anywhere else, and at Scarborough Castle. The two round towers at the angles of the barbacan of York were probably connected by a low breastwork over the gateway. Messrs. Lockwood and Cates consider the whole of the building which projects 56 feet from the gate called Walmgate to be the barbacan.

In cities or towns the barbacan was a watch-tower or outwork, placed at some important point of the circumvallation; thus, Lydgate, in his Bŏke of Troy, speaks of

> "Barbicans and also bulwerkes huge
> Afore the town made for high refuge."

It had sometimes a ditch and drawbridge of its own. (Grose, 'Milit. Antiq.,' vol. ii., p. 2.) The street of London called Barbican received its appellation from its vicinity to a tower of this sort attached to the city-wall: it had been removed when Stow wrote, but some remains of it were visible till the close of the last century. It is in this sense that Ben Jonson uses the term in his Epithalamion ('Works,' vol. vii. p. 5):

> "That far all-seeing eye
> Could soon espy
> What kind of waking man
> He had so highly set, and in what *barbican*."

Spelman ('Gloss.' in v.) says barbacan was a term likewise used for a hole in the wall of a city or castle, through which arrows and darts were cast out. It also signified a long narrow opening left in the walls, to drain off the water from a terrace or platform. In process of time it seems to have been applied to any projecting out-work of a building; at least Florio, in his 'Italian Dictionary' (1598), has "*Barbacane*, an out-work, or corner standing out of a house, a jettie."

The etymology of this word is uncertain. Spelman derives it from the Anglo-Saxon *burgh-kening* (*espiall* from the town); Junius from *burh-beacon* (as if it meant the signal-tower); while Manning, in the Supplement to Lye's 'Dictionary,' expressly says that the word barbican is not Saxon, but derived from the Arabic; first adopted in Italy, and brought to us by the Normans. He says, "Vox ista minime *Saxonica*: scilicet ab Arabibus primo accersitam, et ab *Italis* acceptam, ad nos deduxerunt *Normanni*." Whatever may have been its derivation, there can be little doubt it was received by us from the Normans or French. Its supposed Arabic origin is noticed by Dufresne, 'Gloss.' edit. Francof. 1681, tom. i. col. 473.

BARBACANAGIUM, or BARBICANAGE, was money paid to the maintenance of a barbacan or watch-tower, Cart. 17 Edw. III. m. 6, n. 14; or a tax levied for the same purpose on certain lands. (Grose, 'Antiq. of Eng. and Wales,' pref. p. 9.)

BARBARIAN. The Greek term Βάρβαρος (barbaros) appears originally to have been applied to language, signifying a mode of speech which was unintelligible to the Greeks; and it was perhaps an imitative word intended to represent a confused and indistinct sound. In the 'Iliad,' ii. 867, *καρὶς Βαρβαρόφωνοι*, &c., is rendered by Chapman—

> "The rude unlettered Caribæ that barbarous were of tongue."

Barbaros, it will be observed, is formed by a repetition of the same syllable, *bar-bar-os*. Afterwards, however, when all the races and states of Greek origin obtained a common name, it obtained a general negative sense, and expressed all persons who were not Greeks. (Thucyd. i. 3.) At the same time, as the Greeks made much greater advances in civilisation, and were much superior in natural capacity to their neighbours, the word in question obtained an accessary sense of inferiority both in cultivation and in native faculty, and thus implied something more than the term *ξενός*, or foreigner. At first the Romans were included among the barbarians; and in the time of Plautus the Romans themselves admitted the appellation (Pompeius Festus, lib. ii.), and called themselves barbarians. By degrees they excepted Italy, and at length *barbari* signified all who were not Romans or Greeks. In the middle ages, after the fall of the Western empire, it was applied to the Teutonic races who overran the countries of western Europe, who did not consider it as a term of reproach, since they adopted it themselves, and used it in their own codes of law as an appellation of the Germans as opposed to the Romans. At a later period it was applied to the Moors, and thus an extensive tract on the north of Africa obtained the name of Barbary. [BARBARY, IN GEOG. DIV.]

Barbarian, in modern languages, means a person in a low state of civilisation, without any reference to the place of his birth, so that the native of any country might be said to be in a state of barbarism. The word has thus entirely lost its primitive and proper meaning of *non-Grecian*, or *non-Roman*, and is used exclusively in that which was once its accessary and subordinate sense of *rude* and *uncivilised*.

BARBER-SURGEONS. In former times, both in this and other countries, the art of surgery and the art of shaving went hand in hand. As to the barbiers-chirurgiens in France, see the 'Diction. des Origines,' tom. i. p. 189. They were separated from the barbiers-perruquiers in the time of Louis XIV., and made a distinct corporation.

The barbers of London were first incorporated by King Edward IV. in 1461, Richard duke of Gloucester being one of the founders. At that time the barbers were the only persons who exercised surgery; but afterwards others, assuming the practice of that art, formed themselves into a voluntary association, which they called the Company of Surgeons of London. These two companies were, by an act of parliament passed in the 32 Hen. VIII. cap. xli., united and made one body corporate, by the name of the Barbers and Surgeons of London. This act however at once united and separated the two crafts. The barbers were not to practise surgery further than drawing of teeth; and the surgeons were strictly prohibited from exercising "the feat or craft of barbery or shaving." The surgeons were allowed yearly to take, at their discretion, the bodies of four persons after execution for felony, "for their further and better knowledge, instruction, insight, learning, and experience in the said science or faculty of surgery;" and they were moreover ordered to have "an open sign on the street-side where they should fortune to dwell, that all the king's liege people there passing might know at all times whither to resort for remedies in time of their necessity." Four governors or masters, two of them surgeons, the other two barbers, were to be elected from the body, who were to see that the respective members of the two crafts exercised their callings in the city agreeably to the spirit of the act. There was a surgical museum in their hall when Maitland wrote his 'History of London,' of which he thought very highly.

Holbein commemorated the granting of the charter to the barber-surgeons, in a picture which is still preserved at their hall in Monkwell-street.

The privileges of this company were confirmed in various subsequent charters, the last bearing date the 15th of April, 5 Charles I.

By the year 1745, it was discovered that the two arts which the company professed were foreign to and independent of each other. The barbers and the surgeons were accordingly separated by act of parliament, 18 Geo. II., and made two distinct corporations.

(Pennant's *London*, p. 255; *Stat. of the Realm*, vol. i. p. 794; Edmondson's *Compl. Body of Heraldry*; Strype's edit. of Stow's *Survey of London*, Farringdon Ward within.)

BA'RBITON, in *music*, the name of an instrument in use among the ancients; and that it was a kind of lyre we cannot for a moment doubt, though writers on the subject seem very willing to make it a matter of difficulty. M. Dacier, judging from a passage in Horace (lib. i. carm. 32), concludes that the barbiton was strung with thick flaxen cords. The writer in the 'Encyclopédie Methodique' infers, from the same ode, that the poet means to attribute to Alcæus the invention of the instrument, but it appears to us that he only intends to ascribe to him the invention of lyric poetry. M. de Castilhon is perplexed between Musonius and Athenæus; the one making Terpander, the other Anacreon, the inventor of the barbiton.

BARCAROLLE, in music, a kind of song in the Venetian language, sung by the gondoliers at Venice. Though these airs are composed for the common people, and often by the gondoliers themselves, yet they so abound in melody, that there is not a musician in all Italy who does not pique himself on knowing and being able to sing some of them. The privilege of free entrance to all the theatres in Venice, which these boatmen enjoy (says Rousseau, writing in the middle of the last century), enables them to cultivate their ear and taste, so that to the natural simplicity of their airs they add a degree of refinement which is by no means inconsiderable. The words of these barcarolles are commonly more than natural, partaking of the language employed in the conversation of those who sing them: but such as like a faithful representation of the manners of a people, and have any taste for the Venetian dialect, become passionately fond both of the poetry and music of these popular songs, insomuch that many persons possess large and curious collections of them.

Formerly most of the gondoliers knew by heart the greater portion of 'Gerusalemme Liberata' ('Jerusalem Delivered'), and some the whole poem: they passed the summer nights in their gondolas, singing it in alternate stanzas. Before Tasso, Homer alone had the honour to be thus sung; and no other epic poem has since been equally distinguished. (Rousseau.) But Tasso is now no longer sung by the gondoliers; they still have, however, their songs in response to each other, *improviso*, which the common auditor may be liable (and no doubt willing) to take for Tasso. The old barcarolle was sung in parts, at stem and stern of the same boat, by its own gondoliers.

Barcarolle, or boat-song, comes to us through the French from the Italian *barcarola*. The well known airs 'La Biondina in Gondoletta,' and 'O Pescator dell' Onde,' are pleasing specimens of this species of song.

BARD, an appellation of uncertain etymology, chiefly appropriated to the earliest poets of the Celtic tribes.

Lucan (lib. i. p. 447) describes the office of the bard, and gives his very name:

> Vos quoque, qui fortes animas, belloque peremptas
> Laudibus in longum vates dimittitis ævum,
> Plurima securi fudistis carmina Bardi.
>
> You, too, ye Bards! whom sacred raptures fire
> To chaunt your heroes to your country's lyre;
> Who consecrate in your immortal strain
> Brave patriot souls in righteous battle slain.—Rowe.

Tacitus uses a term, not found in any other writer, which seems derived from the name of bard. He says the Germans used songs, by the recital of which, called barditus, they sought to increase the fury of their warriors, and from the effect of the song drew omens as to the issue of the coming battle. ('Germania,' 3.)

The information, however, which remains to us from classical sources relating to the bards is, for the most part, scanty and detached; Strabo says that the bards (βαρδοι) were singers of hymns and poets among the Gauls. They were, no doubt, originally spread over the greater part of Western Europe, but gave way to southern civilisation; and it is from their latest retreats only, in Wales and Ireland, that we gain our best materials for their history.

Warton says the bards of Britain were originally a constitutional appendage of the Druidical hierarchy. In the parish of Llanidan, in the Isle of Anglesey, there are still to be seen the ruins of an arch-druid's mansion, which they call *Trer Drew*, that is, the Druid's mansion: near it are marks of the habitations of the separate conventual societies which were under his immediate orders and inspection. Among these is *Trer Beird*, or, as they call it to this day, the hamlet of the bards. (Rowland's 'Mona,' pp. 83, 88.) But so strong was the attachment of the Celtic nations (among which we reckon Britain) to poetry, that amidst all the changes of government and manners, even long after the order of Druids was extinct, and the national religion altered, the bards, acquiring a sort of civil capacity and a new establishment, still continued to flourish. And with regard to Britain, the bards flourished most in those parts of it which most strongly retained their native Celtic character. Amongst the Britons living in those countries that were between the Trent or Humber and the Thames, by far the greatest portion of this island, in the midst of the Roman garrisons and colonies, we cannot discover the slightest trace, in the poems of the bards, the lives of the British saints, or any other ancient monument, that they held any correspondence with the Welsh, the Cornish, the Cumbrian, or the Strathcluyd Britons. Amongst other British institutions grown obsolete among them, they seem to have lost that of bards; at least there are no memorials of their having had any, nor any of their songs remaining; nor do the Welsh or Cumbrian poets ever touch upon any transactions that passed in those countries after they were relinquished by the Romans.

And here we see the reason why the Welsh bards flourished so much and so long. But moreover the Welsh, kept in awe as they were by the Romans, harassed by the Saxons, and eternally jealous of the attacks, the encroachments, and the neighbourhood of aliens, were on this account attached to their Celtic manners; this situation and these circumstances inspired them with a pride and an obstinacy in maintaining a national distinction, and in preserving their ancient usages, among which the bardic profession is so eminent. (Warton, 'Hist. Engl. Poet.' vol. i. Diss. 1.) This also will account for their preserving the language in common use, while at the same time the use of the language has perpetuated a succession of minor poets, who have not altogether failed in maintaining the reputation of the older bards by their power and pathos. (Dr. Thomas Price on 'The Literature of Wales.')

By the laws of Hoel Dha, given about the year 940, the *Bardd Teulu*, or court-bard, was a domestic officer. He occupied the eighth place in the prince's court: he held his land free: the prince was to allow him a horse and a woollen robe, the queen a linen garment. At the three principal feasts, Christmas, Easter, and Whitsuntide, he was to sit next to the prefect of the palace, who delivered the harp into his hand; and at the same festivals he was to have the robe of the *disdain*, or steward, for his fee. When a song was required, the bard who had gained the badge of the chair (in musical contest) was first to sing a hymn in glory of God, after that another in honour of the prince, and then the Teuluwr, or bard of the hall, was to sing some other subject. If the queen desired a song, the bard was to attend in her chamber. When he accompanied the prince's domestic servants upon a foray, he was to have an ox or a cow given to him from the booty, and while the prey was dividing he was to sing the praises of the British monarchy. He was also to sing the praises of the British monarchy at the head of the detachment, when drawn up for fight. This, says Pennant ('Tour in Wales,' edit. 1784, vol. i. p. 461), was to remind them of their ancient right to the whole kingdom; for their inroads being almost always on the English territories, they thought they did no more than seize on their own. When invested with his office, the prince was to give the bard a harp, and the queen a ring of gold. Some copies of Hoel Dha's constitutions say a chess-board instead of a harp. The harp was on no account to be parted with. The bard was to lodge with the prefect of the palace. When he went out of the palace to sing with other bards he was to receive a double portion of the largesse or gratuity. If he asked any gift or favour of the prince, he was to be fined by singing an ode or poem; if of a nobleman, three; if of a common person, he was to sing till he was weary, or fell asleep. Any slight injury perpetrated on the royal bard was to be compensated by a fine of six cows and a hundred and twenty pence; his murder at a hundred and twenty-six cows. The marriage-fine of his daughter was estimated at a hundred and twenty pence. Her nuptial present was thirty shillings, and her dower three pounds. (See the 'Leges Wallicæ,' edited by Wotton, fol. Lond. 1730, lib. i. cap. 19, pp. 35, 36, 37.)

The *Pencerdd Gwlad* was another domestic bard of the higher order, who frequented the courts of the Welsh princes, though he was not a regular officer of the household. His privileges are described in the 'Leges Wallicæ,' lib. i. cap. xlv. pp. 68, 69. See also Pennant's 'Tour in Wales,' ut supra, p. 462.

Pennant says, "The bards of Wales were supposed to be endowed with powers equal to inspiration. They were the oral historians of all past transactions, public and private. They related the great events of the state; and, like the Scalds of the northern nations, retained the memory of numberless transactions, which otherwise would have perished in oblivion. They were likewise thoroughly acquainted with the works of the three primary bards, namely Myrddyn ap Morfryn, Myrddyn Emrys, and Taliesin ben Beirdd. But they had another talent, which probably endeared them more than all the rest to the Welsh nobility, that of being most accomplished genealogists, and flattering their vanity in singing the deeds of an ancestry derived from the most distant period."

The Welsh bards were reformed and regulated by Gryffyth ap Conan, king or prince of Wales, in the year 1078. (Warton, 'Hist. Eng. Poet.' dissert. ut supra.)

Pennant gives a minute account of the Eisteddfods, or sessions of the bards and minstrels, which were held in Wales for many centuries: one was held at the town of Caerwys; another at Aberfraw in Anglesea, for the bards of that island and the neighbouring county; and a third at Mathraval, for those of the land of Powis. The reason that these places were thus distinguished was because the two last were the residence of princes; and Caerwys, on account of the royal palace that stood below the town, the residence of Llewelyn ap Gryffydd.

At these eisteddfods, which Pennant terms the British Olympics, none but bards of merit were suffered to rehearse their pieces, and minstrels of skill to perform. These went through a long probation: judges were appointed to decide on their respective abilities; and suitable degrees were conferred, and permissions granted for exercising their talents in the manner already described. In the earlier period, the judges were appointed by commissions from the Welsh princes; and after the conquest of Wales, by the kings of England, notwithstanding that Edward I., according to constant but extremely doubtful tradition, exercised great cruelty over the bards of his time; yet future princes thought fit to revive an institution so likely to appease as well as to soften the manners of a fierce people. The crown had the power of nominating the judges, who decided not only on the merit but the subject of the poems, and as our modern lord chamberlains used to do, were certain of licensing only those which were agreeable to the English court.

A commission for holding an eisteddfod at Caerwys, in 1568, was, in Pennant's time, in the possession of Sir Roger Mostyn, together with the silver harp, which had from time immemorial been in the gift of his ancestors, to bestow on the *chief of the faculty*. This badge of honour was about five or six inches long, and furnished with strings equal to the number of the Muses. The commission, of which Pennant has given the form (as well as an engraving of the harp), is the last which was granted. It was dated 23d Oct. 9 Eliz. In consequence, an eisteddfod was held on the 26th May following, when various persons received degrees, some as chief bards of vocal song, others as primary, secondary, or probationary students; and many more as bards, students, and teachers of instrumental song upon the harp and crwth. Players on crwths with three strings, taborers, and pipers, were reckoned among the ignoble performers; they were not allowed to sit down, and had only a penny for their pains. The degrees consisted of four in the poetical, and five in the musical faculty. For the full details relating to them the reader is referred to Pennant, ut supra, pp. 467-474. The laws of Gryffyth ap Conan recognise the distribution of the classes.

"No public festivity," says Pennant, "great feast, or wedding could be duly solemnised without the presence of the bards and minstrels. A glorious emulation arose among them; and prizes were bestowed on the most worthy. In 1176 the Lord Rhys, prince of South Wales, made a great feast at Christmas, on account of finishing his new castle at Aberteifi, of which he proclaimed notice through all Britain a year and a day before: great was the resort of strangers, who were nobly entertained, so that none departed unsatisfied. Among deeds of arms, and variety of spectacles, Rhys invited all the bards of Wales, and provided chairs for them, which were placed in his hall, where they sat and disputed, and sang, to show their skill in their respective faculties; after which he bestowed great rewards and rich gifts on the victors. The bards of North Wales won the prizes; but the minstrels of Rhys's household excelled in their faculty. On this occasion the Brawdwr Llys, or judge of the court, an officer fifth in rank, declared aloud the victor, and received from the bard for his fee a mighty drinking-horn, made of the horn of an ox, a golden ring, and the cushion on which he sat in his chair of dignity." (Pennant, ut supra, p. 475.)

Since the days of Queen Elizabeth, as has been already said, no royal commission has been issued for holding an eisteddfod; but individual and collective exertions have not been wanting of later years, not only for the revival of the bardic profession, but for the general cultivation and encouragement of Welsh literature. The Gwyneddigion Society was established for this purpose in 1770, and the Cambrian Society in 1818. Annual meetings have also been held for the recitation and reward of prize-poems and performances upon the harp; and another society, since formed, immediately under royal patronage, called The Cymmoridion, or Metropolitan Cambrian Institution.

The Irish carry the history of their bards to the earliest date of the supposed Milesian invasion. The details of that history, in a diffuse form, are given in Walker's 'Memoirs of the Irish Bards,' 4to. Lond. 1786.

These bards were of three classes: 1. The *Ollamhain Redan*, or *Filidhe*, were poets who turned the tenets of religion into verse; they animated the troops before and during an engagement, and raised the war-song. 2. The *Breitheamhain* (Brehons), or legislative bards, who promulgated the laws in a kind of recitative, or monotonous chant, seated in the open air. 3. The *Seanachaidhe* were antiquaries, genealogists, and historians; they recorded remarkable events, and preserved the genealogies of their patrons in a kind of unpoetical stanza. Each province and chief had a Seanacha. Besides these three orders of bards, there was another of an inferior kind, composing the *Cleananaigh*, *Crutairigh*, *Clotairigh*, *Tiompanach*, and *Cuilleaunach*, all of whom took their several names from the instruments on which they professedly played. The head of this order was entitled *Ollamh-Receol*. The profession of these, as well as that of the higher classes of the bards, was hereditary.

Warton says, we are informed by the Irish historians that St. Patrick, when he converted Ireland to the Christian faith, destroyed three hundred volumes of the songs of the Irish bards. Such was their dignity in this country, that they were permitted to wear a robe of the same colour with that of the royal family. They were constantly summoned to a triennial festival, and the most approved songs delivered at this assembly were ordered to be preserved in the custody of the king's historian or antiquary. Many of these compositions are referred to by Keating as the foundation of his 'History of Ireland.' Ample estates were appropriated to them, that they might live in a condition of independence and ease. The possession was hereditary; but when a bard died, his estate devolved not to his eldest son, but to such of his family as discovered the most distinguished talents for poetry and music. Every principal bard retained thirty of inferior note as his attendants, and a bard of the secondary class was followed by a retinue of fifteen. They seem to have been at their height in the year 558. (Keating's 'History of Ireland,' pp. 127, 132, 370, 380, and preface, p. xxiii; Warton, 'Hist. Engl. Poet.' voi. i., Dissert. i. p. 46, note [e].)

According to Warton, the songs of the Irish bards are by some conceived to be strongly marked with the traces of Scaldic imagination, and these traces are believed still to survive among a species of poetical historians, whom they call *tale-tellers*, supposed to be the descendants of the original Irish bards. A writer of equal elegance and veracity relates, that a "gentleman of the north of Ireland has told me of his own experience, that in his wolf-huntings there, when he used to be abroad in the mountains three or four days together, and lay very ill a-nights, so as he could not well sleep, they would bring him one of these tale-tellers, that when he lay down would begin a story of a king, or a giant, a dwarf and a damsel." (Sir William Temple's 'Miscellanea, Part II., on Poetry.') Warton also says ('Dissertation,' i.), "we have already seen that the Scandinavian Scalds were well known in Ireland, and there is sufficient evidence to prove that the Welsh bards were early connected with the Irish. Even so late as the 11th century, the practice continued among the Welsh bards of receiving instructions in the bardic profession from Ireland." When Gryffyth ap Conan, king of Wales, reformed and regulated the Welsh bards in 1078, Powell acquaints us, that he "brought over with him from Ireland divers cunning musicians into Wales, who devised, in a manner, all the instrumental music now there used, as appeareth as well by the books written of the same, as also by the names of the tunes and measures used among them to this day." ('Hist. of Cambr.' edit. 1584, p. 191.)

The harp said to have belonged to Brien Boiromh, king of Ireland, who fell in the hour of victory against the Danes on the plain of Clontarf near Dublin, in 1014, is preserved, as a relic of bardism, in the Museum of Trinity College, Dublin, to which it was presented by the Right Honourable William Conyngham, in 1782.

Spenser ('View of the State of Ireland') gives no favourable idea of the Irish bards of his time. He speaks of them as "so far from instructing young men in moral discipline, that they themselves do more deserve to be sharply disciplined; for they seldom use to choose unto themselves the doings of good men for the arguments of their poems." He continues, "For a young mind cannot rest; if he be not still busied in some goodness, he will find himself such business as shall soon busy all about him. In which, if he shall find any to praise him, and to give him encouragement, as those Bards and Rhymers do for little reward, or a share of a stolen cow, then waxeth he most insolent and half mad with the love of himself, and his own lewd deeds. And as for words to set forth such lewdness, it is not hard for them to give a goodly and painted show thereunto, borrowed even from the praises which are proper to virtue itself. As of a most notorious thief and wicked outlaw, which had lived all his lifetime of spoils and robberies, one of their bards in his praise will say, that he was none of the idle milk-sops that was brought up by the fireside, but that most of his days he spent in arms and valiant enterprises; that he did never eat his meat before he had won it with his sword; that he lay not all night slugging in a cabin under his mantle, but used commonly to keep others waking to defend their lives, and did light his candle at the flames of their houses, to lead him in the darkness; that the day was his night, and the night his day; that he loved not be long wooing of wenches to yield to him, but, where he came, he took by force the spoil of other men's love, and left but lamentation to their lovers; that his music was not the harp, nor lays of love, but the cries of people and clashing of armour; and finally, that he died, not bewailed of many, but made many wail when he died, that dearly bought his death." This song, he adds, when it was first made and sung to a person of high degree in Ireland, was bought (as their manner is) for forty crowns.

The Celtic Highlanders of Scotland had also their bards or sennachies, who sung the deeds of their chiefs; but of their productions there are no genuine remains, though probably portions of Macpherson's Ossian may give a sort of traditional echo of some of them.

The Germans have adopted the word as descriptive of a species of devout battle-song or poem. Klopstock's 'Die Hermanns Schlacht,' 'Hermann und die Fursten,' and 'Hermanns Tod,' are called *barditen*. He had followers, who at first imitated Ossian, and failed; but later poets, as Kretschmann in the epic, and Gerstenberg in the lyric form, have had better success.

(For further information, exclusive of the works already quoted, the reader may consult Evans's *Dissertatio de Bardis*; Jones's *Musical and Poetical Relics of the Welsh Bards, with a History of the Bards and Druids*, 4to. Lond. 1794; Sir Richard Colt Hoare's *Giraldus Cambrensis*, vol. i. p. 300–319; and Beauford's *Origin and Learning of the Irish Bards*.)

BAREGIN. [GLAIRIN.]

BARGAIN. This word is immediately derived into the English language from the French *Barguigner;* and perhaps ultimately from the Italian *Bargagnare*. Its etymology is quite uncertain, but it appears to have been frequently used in the middle ages to signify the arrangement of the terms of a contract of purchase. (See Ducange, 'Glossar.' ad verbum Barcaniare.) In this sense it is commonly used in English law; and when a bargain and sale of goods is mentioned, the bargain denotes the arrangement of the terms upon which one sells and another buys; and the sale expresses the completion of the contract so as to pass the property from the seller to the buyer. In such cases the seller is called the bargainor, and the buyer is termed the bargainee. The two parts of the transaction taken together constitute the whole contract of buying and selling personal goods so as effectually to change the property. In order, however, to give validity to this contract, it is essential that there should be a consideration given or promised by the bargainee to the bargainor. Thus if a man verbally agrees to sell me a horse, and I neither pay him nor promise him any thing for it, this is what the English law, following the civil law, calls *nudum pactum*, a naked bargain, and not a sale, and, being wholly void, will not pass the property in the horse to me.

The term bargain and sale is now much more generally used in a more limited sense to denote a kind of conveyance of real property, which derives its effect from the statute 27 Hen. VIII. c. 10, commonly called the Statute of Uses. For nearly two centuries before that statute, it was the custom throughout England to convey lands to uses: that is to say, the legal possession of them was vested in one person, while the use or beneficial interest was enjoyed by another, who was called the *cestuique use*. This practice is said to have been first introduced by the monastic societies, for the purpose of evading the statutes of mortmain, which, while they prohibited a direct conveyance to those corporations, did not in terms extend to alienations to third persons for the use or benefit of religious houses. This defect was afterwards remedied by the statute 15 Ric. II. c. 5, which rendered uses subject to the penalties imposed by the statutes of mortmain. But the practice of conveying land to uses was found to be attended with so much convenience, that it still continued with respect to estates of private individuals. The courts of common law, indeed, refused to acknowledge any other title than that of the person who was actually in possession of the land. But the Court of Chancery, upon the ground that the legal tenants were bound in conscience to perform the trusts for which the land was vested in them, used to interfere to compel them to account for the profits of the land to the *cestuique use*, and to dispose of it according to his directions.

This was the origin of the jurisdiction of courts of equity over trusts, which has since assumed so extensive and complicated a shape. The interest in the use, being a creation of courts of equity, was of course subject to the modifications imposed by those courts. Hence, they permitted uses to pass by the will of *cestuique use* at a time when land itself was not devisable except by particular custom. Again, uses were not subject to aids, reliefs, wardship, marriage, escheat, or any other feudal incident, nor liable for the debts of *cestuique use*.

The use being, in contemplation of equity, thus separated from the possession of the land, it followed that the alienation of the one might be made without parting with the other. Thus, if a person, possessed of an estate in fee-simple, made a bargain with another that the estate should be his, but retained possession of the property, the Court of Chancery (provided the bargain was grounded upon a sufficient consideration) looked upon the bargainor as holding the estate to the use of the person from whom the consideration proceeded, and who was, according to the dictates of good conscience, to be treated as the real owner of the estate. Equity, however, following the rule of the civil law, not to enforce a *nudum pactum*, refused to compel the performance of any agreements except such as were founded either on *good* or *valuable* consideration. These two classes of contracts gave rise to two new kinds of conveyance, which, though disregarded by the courts of common law, became operative in equity. The first, namely a conveyance on a *good* consideration, was where the owner of the estate, in consideration of an intended marriage, or of the love which he bore his actual wife, child, or other blood relation, agreed by deed to hold the estate for the use of such wife, child, or other blood relation. This was called a covenant to stand seised, from the word 'seisin,' which in English law signifies possession of a freehold estate. The other was where the contract was founded on a *valuable* consideration; namely, one consisting of money or money's worth (as rent, or services incident to feudal tenure), and was called a bargain and sale. It was originally a mere contract for sale; but in process of time it became a mode of settlement of land, in which case the courts of equity did not inquire into the *amount* of the consideration, provided it were *valuable* according to the technical meaning of the term.

In process of time, the inconvenience of separating the real from the ostensible ownership of the land was found to counterbalance any advantages that might have been accidentally derived from the system. The departure from the principles of the common law of England, in permitting secret alienations to have the same effect as the open and notorious conveyances of former times, opened a wide door to fraud. The feudal lords, in particular, suffered by the system of uses to such an extent, that several legislative enactments were from time to time introduced in order to remedy the evil. [USES.] At length the legislature, in the 27th year of the reign of Hen. VIII., by a bold enactment abolished the distinction between ownership of the land and ownership of the use, by transferring uses into possession, that is to say, by giving to the person who had formerly only an interest in the use, a perfect, indefeasible, legal estate in the land.

So that where a person before the statute (having a freehold estate in lands) had agreed, for good or valuable consideration, that the use of such lands should belong to another, the statute divested the bargainor of all interest in the land, and conferred upon the person with whom the contract was made (or, in legal language, the bargainee) the same estate in the land that he formerly had in the use. But it is to be observed, that if the bargainor had an estate less than freehold in the land (as an estate for a term of years), the statute, which provides only for cases where persons are *seised* to the use of others, was held not to apply. Therefore, in that case the bargainee was left to his remedy in equity as before. But in conveyances of freehold estates, the statute gives such a title to the bargainee as he can enforce in a court of law without having recurrence to equity. The operation of the conveyance has been well described to be of such a nature, that the bargain first vests the use, and then the statute vests the possession in the bargainee. The words of the statute extend to every species of real property (except copyhold estates), whether corporeal or incorporeal, whether in possession, reversion, or remainder. Therefore, all such property (if actually in existence at the time of the creation of the use) may be the subject of conveyance by bargain and sale. (Sanders 'On Uses and Trusts,' vol. i. p. 107; and vol. ii. p. 51.)

The legislature having thus given a legal effect to this equitable mode of transfer of property, proceeded in the same session to provide against its being turned into an instrument of fraud. The secret nature of uses had been mentioned in the preamble of 27 Hen. VIII. c. 10, as one of the principal reasons for their abolition. To prevent the same objection from arising to the conveyance by bargain and sale under the statute, the statute 27 Hen. VIII. c. 16, provided that no bargain and sale should operate to pass an estate of freehold, unless made by writing indented, sealed, and enrolled in one of the king's courts of record at Westminster, or with the custos rotulorum, and two justices of the peace, and the clerk of the peace of the county or counties where the lands bargained and sold lay, or two of them at the least, whereof the clerk of the peace was to be one: the enrolment to be made within six months after the date of the writing. The act contains an exception of lands lying within cities, boroughs, or towns corporate, where the mayors or other officers have authority, or have lawfully used to enrol any evidences, deeds, or other writings. A bargain and sale, therefore, of such lands, operates to all intents and purposes, from the date of the conveyance. The writing required by this statute must be a deed; that is, must be delivered as well as sealed, as the requisition that it be indented implies; for the indented edge of the parchment is a symbol of a duplicate of the writing being in the hands of another contracting party: but actual indentation is now unnecessary, provided the deed *purport* to be an indenture, 8 & 9 Vict. c. 106, s. 5. ('Blackst. Com.' vol. ii. p. 336, Dr. Kerr's edit.; and see DEED, INDENTURE.)

The enrolment of a bargain and sale is a copy of the deed upon parchment preserved in the records of the court; and as the statute requires this to be made within six months, without saying *calendar* months, it is understood, according to a well known rule of law, to mean lunar months, consisting each of twenty-eight days. But a recent statute for the abolition of fines and recoveries (3 & 4 Will. IV. cap. 74) provides (s. 41) that bargains and sales made in pursuance of that act shall be good if enrolled within six *calendar* months. The deed may be enrolled upon proof of its due execution, without the concurrence of the bargainer.

As the statute of enrolments obstructs the operation of the conveyance until it be enrolled, frequent questions have arisen in our courts as to the legal rights of the bargainee in the interval between the execution of the deed and the enrolment. For most purposes the enrolment has a retrospective relation to the delivery of the deed, so as to give it the same effect as if the enrolment were immediate. But it has been held that, although the bargainee of a reversion is entitled to the rent incurred between the delivery and the enrolment, yet if the tenant pay the rent to the bargainor, the payment is lawful, and the bargainor is not compellable at law to account for it. Again, it seems that, if a bargainee before enrolment convey the estate by bargain and sale to another person, and then enrol the first deed, the second deed is void, though it be afterwards enrolled. So a lease made by a bargainee before enrolment is not valid. Upon this part of the subject see Saunders 'On Uses and Trusts,' vol. ii. p. 55. The 74th section of the 3 & 4 Will. IV. cap. 74, provides that every deed to be enrolled under that act shall take effect *as if enrolment had not been required*, but shall be void against a purchaser for valuable consideration claiming under a deed subsequent in date but enrolled before the other.

Enrolments of bargains and sales of freehold land being considered as deeds of record have been deemed so far worthy to be assimilated in their nature to records as to render a copy of an enrolment admissible, in the first instance, as evidence in a court of law, without any actual proof of its execution. This cannot be the case with any other kind of deed, except where the original is in the possession of the adverse party, who refuses, after notice given, to produce it. But stat. 10 Anne, c. 18, s. 3, in conformity (as it is said) with former usage, has given to enrolments of deeds of bargain and sale the same privilege with other records, by making copies of them of the same force, when produced in evidence, as the originals. Such copies must be examined with the enrolments and signed by the proper officer (whence they are called office copies), and must be proved upon oath to be true copies so examined and signed.

Some time after the passing of the Statute of Enrolments a method of evading the object of it was discovered. The statute, in terms, only extends to conveyances of estates of freehold or inheritance. Therefore if a person, being himself possessed of an estate of freehold (for otherwise, as we have mentioned above, the Statute of Uses itself did not apply), carved an interest for a term of years out of such estate by deed of bargain and sale, such deed did not require enrolment. And the Statute of Uses conferring upon such bargainee for years the legal possession of the land, he was in a condition to receive from the bargainor a release of the freehold reversion: for a release is a relinquishment of right, and by the rules of the common law can only be made to a person who has already some interest in the land, which enables him to avail himself of the right relinquished. [RELEASE, REVERSION.]

This was the origin of the now disused conveyance by lease and release, which, from its convenience in effecting a transfer of the legal freehold by the rules of the common law, without any additional ceremonies, had, at one time and until very recently, nearly superseded every other mode of alienation of freehold property. The modern conveyance by lease and release was a transaction compounded of a bargain and sale and a release at common law, in which two deeds were required. The first, which was generally a lease by bargain and sale for one year for a nominal consideration, by force of the Statute of Uses, gave the actual legal possession of the land, without a formal entry, to the bargainee. The second, which generally bore date the day after the date of the lease, was a deed of release of the freehold and inheritance of the land to the party who had already obtained possession by virtue of the lease for a year. For a further account of this mode of conveyance, see LEASE and RELEASE.

It is to be observed, however, that as before the Statute of Uses it was a rule of law that a corporation could not be seised to a use, so since that statute no corporation (even though otherwise not disabled in law from alienation) can convey by bargain and sale. Therefore such a corporation, in order to convey by lease and release, had to make a lease operating at the common law; in which case an actual entry upon the land by the lessee and payment of rent was to be made before the lessee had such a possession as to enable him to take a release of the reversion.

The operative words of transfer commonly used in a deed of bargain and sale are 'bargain and sell;' but it seems that if a man, for a pecuniary consideration, by deed indented, covenant to stand seised to the use of another, or give and enfeoff, or alien, grant, and demise to him, such deed, if properly enrolled, will operate as a bargain and sale. (Sanders, 'Uses and Trusts,' vol. ii. p. 49.)

A bargain and sale, as well as a lease and release, is said to be a harmless conveyance, that is, if a person by either of these modes of conveyance professed to grant a larger interest than he actually possessed in the land (as where a tenant for life attempted to convey the fee), the conveyance operated only to pass such interest as the grantor could lawfully convey. But if such tenant for life had formerly attempted an alienation by a more violent mode of conveyance (as by feoffment), a forfeiture of the life estate ensued, and the person next in remainder or reversion was entitled to take advantage of such forfeiture by an immediate entry upon the lands.

The act 8 & 9 Vict. c. 106, took away from the feoffment its tortious operation. The conveyance by bargain and sale has now become disused, the mode of transfer by lease and release having been superseded by simpler methods of transfer. All property can now be conveyed by a simple deed of grant, which requires in ordinary cases no enrolment, 8 & 9 Vict. c. 106, s. 2.

BARGE-BOARD; BARGE-COURSE. Barge-course is a term applied to that part of the tiling of a roof which projects over the gable end of a building. The under part of the barge-course, immediately over the external wall of the gable, is commonly stuccoed, and to protect this stucco from the weather, two boards, called *barge-boards*, following the inclination of the roof, are usually attached to the gables of old English houses, fixed near the extremity of the barge-course, and carved in the richest manner. These barge-boards may be considered as one of the peculiar characteristics of domestic Gothic architecture. Barge-boards were also placed on the ends of the gables of church-porches, when these were constructed of wood. Examples still remain of barge-boards of the 14th century, which are marked by the quiet richness characteristic of the carved-work of the English ecclesiastical architecture of that period. In the succeeding century they were less ecclesiastical in style; the cusps which were usual in the earlier ones were in the 16th century omitted, and the barge-board bore a hip-knob, which was carried upwards as a finial and downwards as a pendant: sometimes, however, the pendant only was used. Numerous fine examples of these barge-boards may be seen at Coventry, Shrewsbury, Oxford, Salisbury, and other towns which retain examples of our older domestic architecture. (See Pugin's 'Ornamental Gables,' in which the rich designs of many of these carved boards are admirably drawn.)

The word barge has been supposed to be a corruption of *bash*, which is used provincially to express beating in, beating on, and beating down; the barge-board being placed at the gable ends of buildings to protect the barge-course from the rain, which would otherwise beat in upon it: *barge*-board might, it was thought, therefore possibly be a corruption of *bash*-board. But it is perhaps more likely to be a corruption of *verge*-board. It sometimes occurs as *parge*-board, and may have been so called from its protecting the parget or plaster of the barge-course.

BARILLA, the commercial name given to the impure carbonate of soda formerly imported into this country, principally from Spain, the Canary Islands, and Sicily. The best was brought from Alicante, in the neighbourhood of which place it was prepared from two plants, the *salsola sativa*, or barilla, whence the name of the preparation, and the *salier*. These plants were very extensively cultivated in Valencia and Murcia, and the produce was annually exported from Alicante to the amount of 90,000 cwt. By far the largest proportion of this quantity found a market in this kingdom. The plants are raised from seed which is sown at the close of the year, and they are usually in a fit state to be gathered in the month of September following. They are then plucked up by the roots, and after they have been allowed to become heated by being thrown together in heaps, are dried in the sun by the same method as is used in England for making meadow-hay. In October the plants are burned. For this purpose, hemispherical holes are made in the earth capable of containing about a ton and a-half of soda; two iron bars are laid across each of these cavities, and the dried plants, mixed with straw and reeds, are placed upon these supports. The whole is then set on fire, when the soda which the plants contain is fused and flows into the cavity beneath in the form of a red-hot fluid. This burning is continued by the constant heaping on of plants until the pit is filled, when the alkali is covered over with earth and left to cool gradually, during ten or twelve days. At the end of that time the mass is found to be of a hard and spongy consistence; and this, when broken into fragments, is ready for shipment. Barilla of the best quality is of a bluish-gray colour; that which is made from other plants, and which is inferior, is of a colour approaching to black, and of greater specific gravity than barilla made from the plants above-named.

From 1829 to 1834 the importation of barilla into Great Britain for the manufacture of soap and glass averaged 252,000 cwts. Now little or none is imported. This change has been occasioned by the production of carbonate of soda from common salt, through the agency of sulphuric acid; salt having become much cheaper from the repeal of the duty, and sulphuric acid also from improvements in the manufacture. The quantity of carbonate of soda now consumed annually is calculated to be at least seven times as much as the largest importations of barilla in any single year. [SODA, MANUFACTURE OF.]

BA'RIUM (Ba), a peculiar metal, the basis of the alkaline earth baryta. Davy first gained indications of the decomposition of baryta in the end of October 1807; he obtained an alloy of it with iron in March 1808; and in the beginning of June, in the same year, he obtained the metal. To prepare barium, a quantity of the mineral substance called carbonate of baryta is made into a paste with water, and placed on a plate of platinum; a cavity is made in the paste to receive a globule of mercury; the mercury is rendered negative, the platinum positive, by means of a Voltaic battery containing about one hundred double plates. In a short time, the baryta of the carbonate is decomposed, and an amalgam of mercury and barium formed. This amalgam must be heated in a small bent glass tube, which contains no lead, and filled with hydrogen gas, or the vapour of naphtha; the mercury being volatilised, the barium remains. Barium may also be procured, without the aid of electricity, by passing a current of the vapour of potassium over red-hot baryta in an iron tube. By this a mixture of barium and oxide of potassium is obtained; from this the metal is to be extracted by amalgamation with mercury, and the amalgam is to be decomposed by heat in the mode already described. These methods do not give the metal in a state of purity, but it may be obtained pure by the voltaic decomposition of its fused anhydrous chloride.

Barium is a yellow metal of considerable lustre. It is much heavier than water, for it sinks even in sulphuric acid, though surrounded by bubbles of gas. It decomposes water readily, with the evolution of hydrogen gas; a solution of baryta is thus obtained. By exposure to the air, it is slightly covered with a crust of baryta; it fuses before it becomes red hot, and at this temperature it acts upon glass, without being volatilised. When exposed to the air, and moderately heated, it burns with a deep red light. It may be flattened a little, so that it is to a certain extent a malleable metal. Barium has however as yet been obtained only in small quantities, and consequently its properties are but imperfectly known. The equivalent of barium is 68·64. Barium forms two compounds with oxygen,—a protoxide and a binoxide.

Protoxide of Barium (BaO); *Baryta*; *Barytes*.—This oxide in combination occurs largely in nature, and was discovered in the year 1774 by Scheele; its name is derived from βαρὺς (*barys*), heavy. Baryta is met with combined with sulphuric acid, forming *heavy spar* or *cawk*, termed chemically sulphate of baryta, and with carbonic acid, constituting the mineral termed *witherite*, or carbonate of baryta; it may be procured by decomposing either of these native compounds. The simplest mode, when it is wanted free from water, is to convert the carbonate into nitrate of baryta, and this when strongly heated in an earthen crucible is decomposed, and the nitric acid being expelled, the baryta remaining has the following properties:—It is of a grayish-white colour. When moistened with water it becomes very hot, and in a short time falls into a fine white powder; if more water is added, it becomes a crystalline and very hard mass. The specific gravity of baryta is about 4·0; it is extremely poisonous, has an acrid, alkaline, caustic taste, and requires a high temperature to fuse it.

Baryta, or the protoxide of barium, is composed of

1 equivalent of oxygen	8
1 do. barium	68·64
	76·64

Baryta and water combine and form at least two compounds: the first hydrate, is procured when a small quantity of water is poured upon baryta, and during their action, as has been already stated, much heat is evolved, and the baryta becomes a white powder. This hydrate contains one equivalent of water; it is fusible at a red heat, but does not part with its water even when heated to whiteness.

According to Davy, 20 parts of water at 60° dissolve one part of baryta: the solution is called *baryta water*, and is frequently used as a chemical re-agent. With carbonic acid baryta forms an insoluble carbonate, and both baryta and baryta water speedily acquire carbonic acid by exposure to the air. Baryta water acts strongly as an alkali, converting vegetable yellows to brown, restoring the blue colour to reddened litmus, and saturating acids. Water at 212° dissolves, by Davy's experiments, half its weight of baryta, of which a considerable portion separates in the state of crystals as the solution cools; these crystals contain ten equivalents of water.

Peroxide of Barium (BaO_2), *Binoxide of Barium*, is prepared by heating baryta to low redness in a platinum crucible, gradually adding to it about one-fourth of its weight of chlorate of potash; this yields oxygen to the baryta or protoxide of barium, which thus becomes peroxide, but mixed with chloride of potassium, which may be dissolved by cold water, while the peroxide of barium remains undissolved, combined with water; it may also be prepared by passing oxygen gas over baryta heated to redness. It is composed of two equivalents of oxygen and one equivalent of barium. It is decomposed by acids, and is used only in preparing the binoxide of hydrogen.

Neither nitrogen nor hydrogen unites with barium.

Chloride of Barium (BaCl + 2HO).—Chlorine and barium combine to form one chloride, consisting of

1 equivalent of chlorine	35·47
1 do. barium	68·64
	104·11

The best mode of preparing chloride of barium is to dissolve carbonate of baryta in hydrochloric acid, and evaporate the solution so as to obtain crystals, which should be then purified by re-crystallisation. Chloride of barium is a colourless salt, soluble in water, but insoluble in alcohol. Five parts of water at 60° dissolve one part of chloride of barium. Chloride of barium is used as a chemical re-agent for the detection and quantitative determination of sulphuric acid.

Protosulphide of Barium (BaS).—Sulphur and barium combine in several proportions, but the protosulphide is the only compound of importance. It may be prepared by heating together finely-powdered sulphate of baryta and powdered charcoal in a covered crucible; in this case the charcoal takes oxygen both from the sulphuric acid and the baryta, and protosulphide of barium remains, which dissolves readily in boiling water, and the solution on cooling deposits colourless transparent crystals; these crystals are protosulphide of barium, containing six equivalents of water.

Protosulphide of barium thus prepared is much used for the production of other salts of barium, as it is readily decomposed by all acids, even the carbonic acid. Thus chloride of barium may be formed by adding hydrochloric acid to protosulphide of barium.

$$\text{BaS} + \text{HCl} = \text{BaCl} + \text{HS}.$$

Phosphide of Barium (BaP).—*Phosphuret of Barium*.—Phosphorus and barium combine to form the phosphide, by heating baryta to redness in a glass matrass with a long neck, and throwing phosphorus upon it. There are formed both phosphate of baryta and phosphide of barium, as represented in the following equation:—

$$\underbrace{7\text{BaO}}_{\text{Baryta.}} + 6\text{P} = \underbrace{5\text{BaP}}_{\substack{\text{Phosphide of}\\ \text{Barium.}}} + \underbrace{2\text{BaO}, \text{PO}_5}_{\substack{\text{Phosphate of}\\ \text{Baryta.}}}$$

The mass fuses, and on cooling has a brown colour and a metallic lustre. When too strongly heated the phosphide of barium is decomposed, phosphorus is volatilised, and baryta remains. Phosphide of barium decomposes water; phosphuretted hydrogen gas is evolved, and hypophosphite of baryta remains in solution.

Iodide of Barium (BaI).—Iodine and barium unite and form the iodide of this metal. It may be prepared by acting upon baryta or its carbonate with hydriodic acid, and evaporating the solution obtained. It is very soluble in water, and crystallises in acicular crystals, which deliquesce slightly by exposure to the air.

Bromide of Barium (BaBr + 2HO).—Bromine and barium, when combined, form the bromide. It may be obtained by boiling excess of moist carbonate of baryta in a solution of protobromide of iron; the filtered solution is to be evaporated to dryness and the residue made red hot; by dissolving this in water, and by careful evaporation, colourless rhombic crystals are obtained, which are soluble in alcohol.

Fluoride of Barium (BaF).—Fluorine and barium may be made to combine by digesting fresh precipitated and moist carbonate of baryta in hydrofluoric acid; the carbonate is decomposed, and the fluoride of barium is formed, and separates in the state of a white powder. This may be heated to redness without decomposing, and is slightly soluble in water. The solution, by evaporation, yields crystalline grains, which are readily dissolved by hydrochloric and nitric acids.

Having described the principal binary compounds of barium, we proceed to notice the more useful of the numerous salts formed by combining the protoxide of barium (baryta) with different acids. The following are the only barytic salts which are extensively employed.

Acetate of Baryta ($BaO, C_4H_3O_3 + 3HO$).—This salt may be prepared by dissolving either baryta or the carbonate in acetic acid, or decomposing the solution of protosulphide of barium with it. By evaporation, crystals of acetate of baryta are obtained in slender prisms, resembling those of acetate of lead. These crystals effloresce by exposure to the air; they dissolve in 1·75 part of cold water, and in 1·03 of boiling water; 100 parts of cold alcohol dissolve one part of these crystals, and when boiling, one part and a half. This salt is composed of

1 equivalent of acetic acid	51·0
1 do. baryta	76·6
3 do. water	27·0
	154·6

The taste of this salt is saline and bitter. It is decomposed by the fixed alkalies and their carbonates, and by carbonate of ammonia; it is also decomposed by sulphuric acid and the sulphates, which precipitate sulphate of baryta.

According to Mitscherlich, when this salt crystallises at the temperature of 55° Fahrenheit, it contains only 6·6 per cent. of water; but when below this temperature it contains, as above stated, about 17·5 per cent. of water of crystallisation.

Carbonate of Baryta (BaO, CO_2).—This substance occurs to a considerable extent as a mineral product, and is by mineralogists sometimes called *witherite*. It is a dense substance, its specific gravity being about 4·331; it is sometimes translucent and nearly colourless, but is often opaque. It sometimes occurs crystallised, and the primary form is a right rhombic prism, but it usually has the form of a six-sided prism.

Carbonate of baryta is so nearly insoluble in water as to require about 4300 times its weight at 60°, and 2300 at 212° for solution; and it is still more insoluble in water containing any salt in solution. It is poisonous, and suffers no change by exposure to the air. When heated to whiteness with charcoal it is decomposed, and on the addition of water a solution of baryta is obtained. It consists, according to Dr. Thomson, of

1 equivalent of	carbonic acid	. . . .	22·0
1 do.	baryta	. . . . . .	76·6
			98·6

It is used for the purpose of dissolving in various acids to procure barytic salts, and, when heated with charcoal, also for preparing baryta, especially when it is wanted merely in solution in water. Bicarbonate and sesquicarbonate of baryta may be formed, but they are unimportant compounds.

Nitrate of Baryta (BaO, NO_5) is readily procured by adding nitric acid either to baryta, its carbonate, or to the solution of protosulphide of barium. The solution is colourless, and by evaporation yields crystals, the form of which is the regular octahedron.

This salt requires 12 times its weight of water at 60° for solution, and between 3 and 4 times its weight at 212°. It is not altered by exposure to the air, but when strongly heated it is, as already noticed, decomposed, and baryta remains in a pure state. This salt consists of

1 equivalent of	acid	. . . . . .	54·0
1 do.	baryta	. . . . . .	76·6
			130·6

The crystals contain no water.

Sulphate of Baryta (BaO, SO_3); *Heavy Spar.*—This compound occurs largely in many parts of Great Britain, especially in the lead-mines of the north of England. It occurs both amorphous and crystallised. In the former state it is sometimes colourless and transparent, but frequently opaque. The crystals are often very large, and the primary form, subject to many varieties, is a rhombic prism. It is extremely heavy, its specific gravity being about 4·7. It is unalterable in the air, insipid, and insoluble in water; indeed, strong sulphuric acid is the only fluid which dissolves it in any notable quantity, and from this it is precipitated by water. It is composed of

1 equivalent of	sulphuric acid	. . . .	40·0
1 do.	baryta	. . . . . .	76·6
			116·6

Sulphate of baryta may also be prepared artificially by adding either dilute sulphuric acid or any soluble sulphate to a solution containing baryta or any of its salts. The sulphate of baryta precipitates as a heavy white powder, insoluble in water, acids, and alkalies.

Heat produces no decomposition in sulphate of baryta; but, as already noticed, when heated with charcoal it is converted into sulphide of barium. When boiled also in a solution of carbonate of potash, a portion of it is converted into carbonate of baryta; but the decomposition takes place only to a limited extent.

On account of the extreme insolubility of sulphate of baryta, its constituents are delicate tests of each other's presence, and both sulphuric acid and baryta are almost invariably converted into this salt when their weight has to be estimated in quantitative analysis.

When sulphate of baryta is moderately heated with carbonaceous matter, a substance is produced called *Bolognian phosphorus*, which possesses the property of exhibiting luminosity in the dark for some time after it has been exposed to the direct rays of the sun.

BARIUM, SALTS OF. [BARIUM.]

BA'RIUM, CHLORIDE OF—*Medical Properties of.*—This compound never occurs native, but is always obtained either by the decomposition of the native carbonate of barytes, or witherite, as directed by the London Pharmacopœia, or of the sulphate, or heavy-spar, as directed by the Edinburgh College. This last seems the preferable mode, not only from the abundant occurrence of heavy-spar, but because the salt so procured is generally purer (Christison); and as it is more employed as a chemical test than in medicine at the present day, purity is an essential condition for its utility. It crystallises in white, transparent, shining, right rhombic prisms, sometimes in double eight-sided pyramids, or, by rapid evaporation, in thin plates (Geiger). It is permanent at the ordinary temperature of the air, but efflorescent in a very dry atmosphere. Its specific gravity is 2·825. It is of easy solubility in water: 100 parts dissolve 43·5 at 60° Fahr.; at 212°, 78 parts. Pure alcohol does not dissolve any of it; rectified spirit, a minute quantity. The only officinal preparation is the watery solution, Liquor Barii Chloridi.

Chloride of barium possesses acrid-narcotic properties, its taste being irritating and burning. It resembles medicinally chloride of calcium, but is more potent; in poisonous doses its action is similar to arsenic, with this difference, that it requires a larger dose to destroy life, and while its local action is less marked, producing less disintegration of the stomach, it is more rapidly absorbed and produces death more speedily. It is rarely employed as a means of self-destruction, or of intentional injury to others. Fortunately an efficient antidote exists in agents readily procured, and invariably efficacious if speedily administered. Any alkaline sulphate, such as Epsom or Glauber salts, or sulphuric acid greatly diluted, will instantly form an insoluble and harmless sulphate of barytes. Medicinally this compound is employed in very minute doses in various forms of scrofula. It possesses slight tonic powers, improves the appetite, and promotes absorption, reducing the glandular enlargements. It once enjoyed, chiefly from the testimony of Hufeland, a high celebrity. But like many other muriates once confided in for the removal of scrofula, it has almost fallen into disuse, particularly since iodine has become known. Some practitioners, thinking that two agents which are thought singly to be of use, must do good when combined, have formed an iodide of barium. This salt has a disagreeable nauseating taste. It is given in the dose of the eighth of a grain, in some aromatic water, three times a day. An ointment is also formed of it.

Pure air, exercise, regular, and above all early hours, appropriate diet, and other points of regimen, such as warm clothing, will do more to eradicate scrofula than any medicines.

(Lugol, *On Scrofula*, translated by Ranking, 1844.)

BARK. There are several kinds of bark which enter largely into commerce, and are used for processes in the arts, or for medicines. The principal kinds in the first of these classes are the barks of the oak, the cork, the mimosa, and the quercitron. Among the descriptions of bark used for medicines we shall notice only that known under the name of Jesuits' or Peruvian Bark: the others are not of much commercial importance. Some other kinds of bark, as Cinnamon and Cassia, will be noticed in other parts of this work.

Oak Bark.—(German, *Eichenrinde Lohe;* Dutch, *Run, Runne;* Danish, *Bark, Garverbark;* Swedish, *Bark, Ekbark;* French, *Tan Brut, Ecorce de Chêne;* Italian, *Scorza di Quercia—Corteccia della Quercia;* Spanish, *Corteza de Encina;* Portuguese, *Casca do Carvalho;* Russian, *Dubowui Kora;* Polish, *Dab Garbarski;* Latin, *Quercus Cortex.*) For a long time, oak-bark was the only substance used in England for the process of tanning; and it was thus employed for ages, without the tanners knowing what were the properties of the substance which produced the chemical change whereby hides are converted into leather. The increasing demand for oak-bark beyond the means of supply so raised its marketable value, that an investigation became necessary, in order to ascertain whether, when the nature of those properties was discovered, some cheaper substances might be found to answer as substitutes. Other substances besides oak-bark had before that time been used for tanning in certain foreign countries; such as heath, gall-nuts, birch-tree bark, myrtle-leaves, leaves of wild laurel, and willow-bark. In 1765 oak saw-dust was applied with some success in England to the purpose of tanning; and this plan has been since pursued in Germany.

The result of investigations showed that the tanning power of oak-bark resided in a peculiar astringent substance, to which, from the use to which it is applied, the name of *tannin* has been given. In more recent times, Sir Humphry Davy determined, by a series of experiments, the relative value to the tanner of different substances in which tannin is found; and he has shown that 8½ lbs. of oak-bark are, in this respect, equal to 2½ lbs. of galls, to 3 lbs. of sumach, to 7½ lbs. of bark of the Leicester willow, to 11 lbs. of bark of the Spanish chestnut, to 18 lbs. of elm-bark, and to 21 lbs. of common willow-bark.

To prepare oak-bark for use, it is ground to a coarse powder between cast-iron cylinders, or in bark-mills which implement makers have lately invented. In the ground state it is put into the tan-pit, in alternate layers, with the skins to be prepared. A better method sometimes employed is to make an infusion of the bark in water, which dissolves and holds the tannin. The action of this substance upon skins may be explained in a few words. Before the skin is subjected to the tanning process, the hair, epidermis, and any fleshy or fatty parts adhering to them, must be removed; the remainder consists wholly of gelatine, a substance capable of being dissolved in water, and which then forms the substance well known as glue. Tannin, as we have seen, is likewise readily soluble in water; but the two substances, when brought together, form the insoluble and imputrescent compound called leather. See further on this subject under TANNING.

It has been found that the proportion of tannin which oak-bark contains varies materially according to the season in which it is cut. If taken in the spring, it has four and a half times the quantity, in a given weight, compared with what it would have if cut in winter. Sir Humphry Davy likewise discovered that the proportion is influenced by the age of the tree, tannin being more abundant in the bark of young than of old trees.

There are no means of knowing what quantity of oak-bark is used annually by the tanners of this country. Of that which is imported, about half comes from Holland and Belgium.

Cork Bark.—This substance is described in a separate article. [CORK AND CORK-CUTTING.]

Mimosa, or Wattle Bark.—This bark is collected from two species of the mimosa, which are plentifully found in New South Wales, Van Diemen's Land, and New Zealand, where, at least in the British settlements, it is used for the manufacture of leather. This bark contains about 150 lbs. of pure tannin in every ton weight, which is only about three-fifths of the proportion yielded by the best white oak bark. It is also said that it gives a reddish colour to the leather, which, although it does not actually lower its value in use, creates a prejudice against it in the market. As long ago as 1823 a small quantity of fluid extract of this bark was brought to London from Australia, and, after having been subjected to trial by some tanners, was purchased by them. Since that time, importations of the bark in its crude state, as well as in the form of an extract, have continually been made.

Quercitron Bark.—This name has been given to the bark of a description of oak, the *Quercus nigra*, or *tinctoria*, which is a native of North America. It is used as a dye stuff for imparting a yellow colour, the different shades of which depend upon the choice of the substance employed as a mordant. This bark was first brought into use in England by Dr. Bancroft, who obtained an exclusive patent for its application to this purpose. The colouring matter resides wholly in the inner bark of the tree; the outer bark is therefore removed previous to its being packed in casks for shipment. Quercitron bark which has been previously ground in a mill, gives out its colouring matter to water when heated to the temperature of 100° Fahr. If a higher degree of heat be used, the *tannin* which the bark contains will also be dissolved, and this will impart a brown tinge to the dye which it is desirable to avoid. For this reason the dye must always be separated from the bark before it is used. The colouring matter obtained from the quercitron-bark of commerce is equal to that yielded by eight or ten times its weight of weld.

Peruvian Bark.—German, *Chinarinde, Fieberrinde*; Dutch, *Kina, Quinquina*; Danish, *Kina, Chinabark*; Swedish, *Feberbark*; French, *Quinquina*; Italian, *China*; Spanish, *Quina*; Portuguese, *Quinquina*; Russian, *Chinchina*; Polish, *Kwinkwinna*; Latin, *Cinchona, Cortex Peruvianus.* Three principal species of this bark are known in commerce, namely, the pale, the red, and the yellow. The first of these, the original cinchona of Peru, is now become scarce. It is the produce of the *Cinchona lancifolia*, and is imported in chests, each containing 200 lbs. weight, and carefully covered with skins. It comes in quilled pieces from 8 to 10 inches long, and of various thicknesses. Internally the colour is of a pale fawn or cinnamon hue, but when moistened the bark assumes a pale orange colour. It is nearly odourless when dry, but is very sensibly aromatic while under the process of decoction. The *red* bark is taken from the *Cinchona oblongifolia*, which is found growing on the Andes. It is imported in various-sized pieces packed in chests, containing each from 100 to 150 lbs. Its colour is that of a reddish brown; its taste is not so bitter as that of the pale variety, but greatly more astringent. The *yellow* bark was first brought into use in England about the year 1790: it is obtained from the *Cinchona cordifolia*, which grows at Quito and Santa Fé. This variety is imported in pieces, some quilled and others flat, of from 8 to 10 inches in length, packed in chests containing from 90 to 100 lbs. each. The colour approaches to that of an orange; it gives out, in decoction, an odour very similar to that of pale bark; its taste is more bitter, but it is not astringent. Its goodness is judged of by the colour. If it loses its orange tint, and takes that of pale yellow, it is not so valuable, and it is still worse when of a dark colour, between red and yellow.

It is said that the native Indians were unacquainted with the medicinal virtues of this bark, and that its efficacy in cases of fever was accidentally discovered by the Jesuits, whence the name, by which it is very generally known, of Jesuits' bark. It was first brought to Europe in 1632, but more than half a century elapsed thereafter before its use became at all extensive in this quarter of the world. Humboldt states that from 12,000 to 14,000 quintals, or cwts., are annually exported from Peru.

During the three years ending with 1858, the average quantity of tanners' bark imported was 365,000 cwts. annually—duty free.

BARK.—*Medical Uses of.*—[CINCHONA.]

BARK-BED, in horticulture, is a bed formed of the spent bark used by tanners, placed in the inside of a brick pit in a glazed house, constructed for forcing, or for the growth of tender plants.

The object of a bark-bed is to produce artificial warmth by the fermentation of the materials of which it consists, and at the same time to keep the atmosphere of the house constantly damp. Gardeners use it for all plants which require what they call bottom heat; that is to say, for all species which are natives of tropical climates, and for pineapples especially; but it is not employed in the cultivation of greenhouse plants, except sometimes for striking their cuttings. [CUTTINGS.]

In constructing a bark bed, the coarsest bark which can be obtained after the tanners have used it should be selected, because it is found that the slowness of the fermentation, and consequently the steadiness of the heat given off, is in proportion to the size of the fragments of bark employed: small tan, broken into minute pieces by machinery, although often the only material to be had, should consequently never be used if it can be avoided. After having been slightly dried by being spread in the sun, the tan is first laid in heaps, covered with mats, until fermentation has commenced; it is then transferred to the brick pit, in which it is finally to remain. Having been lightly but evenly arranged in the pit, and the glass roof of the house having been closed, the tan is left to undergo fermentation; which at first is violent, evolving more heat than any plants could bear. But in a few days it subsides; and when the temperature of the bed has fallen to 96°, it is in a proper state to receive the pots, which are to be plunged in it. The heat will gradually, but very slowly diminish to 60°, below which it is scarcely desirable, in the opinion of gardeners, that the tan should be retained; but the temperature may a second time be raised to 70° or 80°, by turning the tan over, or fermentation may be further renewed by the addition of a small quantity of yeast. The temperature of the tan is generally judged of by feeling the end of a stick which is thrust into the centre of the bed; but as it is impossible to use so rude a test as this with any accuracy, it is now more customary to employ what is called a Breegazzi's thermometer introduced into the hollow end of a pole, and thus protected from being broken when thrust into the tan.

It is, however, found that, after procuring the best kind of material, the heat of a bark-bed cannot be maintained so steadily or so long as is desirable; and it has been recommended to substitute fallen oak-leaves, which can easily be collected in the autumn. These ferment much more slowly than oak-bark, and never acquire so high a temperature as the maximum of that substance; and as they are less expensive, they should always be used when they can be procured. It is, however, to be remembered, that no other leaves than those of the oak, or of some other plant equally abounding in tannin, answer the purpose so well.

Notwithstanding the quantity of heat given out by a bark-bed, it is always found necessary to employ some other mode of warming a house in addition—either by smoke-flues, or hot-water, or steam-pipes; and this being the case, and such contrivances being of themselves sufficient to raise the atmosphere to any temperature that can be required, a question has been started, whether a bark-bed is really of any use. We have already stated that the object of a bark-bed is to produce artificial warmth by fermentation, and moisture in the atmosphere by parting with its water. So far as these objects go, they can certainly be abundantly and more efficiently supplied by other means: the warmth by flues or water-pipes, and the moisture by open tanks, or by steam-cocks, or by watering the floors and walls of a hot-house. But there still remains what gardeners call *bottom-heat*—that is to say, a steady temperature around roots somewhat higher than that of the atmosphere surrounding the stem and leaves. All experience shows that this is of the first importance in gardening, as indeed was to be expected when it is considered that the mean temperature of that part of the soil in which plants grow is universally something higher in nature than that of the air itself; so that in all cases plants are stimulated by some amount of bottom-heat. Thus, even near London, the average temperature of garden-ground at two feet below the surface is in March 41°·57 (Fahr.), while the mean temperature of the atmosphere in that month is only 40°·49. See Lindley's 'Theory and Practice of Horticulture,' 2nd ed. book ii., chap. i., where this subject is fully discussed.

BARLEY is a grain too generally known to require a minute description. It is readily distinguished from other grain by its pointed extremities, and by the rough appearance of its outer skin, which is the corolla of the flower closely enveloping the seed, and, in most varieties, adhering strongly to it.

Barley belongs to the family of the *Gramineæ*: its botanical characters are described in the article HORDEUM, in NAT. HIST. DIV.

According to the most ancient authors, barley formed a principal part of the food of man in the early ages, and it continues to do so at this day, in many countries where the progress of agriculture and the increase of wealth have not yet enabled the inhabitants to exchange the coarser barley loaves for the more palatable and nutritious wheaten bread, and where the soil is not well adapted to rye, or the climate to maize.

Of all the cultivated grains, barley is perhaps that which comes to perfection in the greatest variety of climates, and is consequently found over the greatest extent of the habitable world. It bears the heat and drought of tropical regions, and ripens in the short summers of those which verge on the frigid zone. In genial climates, such as Egypt, Barbary, and the south of Spain, two crops of barley may be reaped in the same year, one in spring from seed sown the preceding autumn, and one in autumn from a spring sowing. This explains a passage in Exodus (ix. 31), where the effect of the hail is mentioned which desolated Egypt, in consequence of the refusal of Pharaoh to let the children of Israel depart: "The flax and the barley were smitten, for the barley was in the ear, and the flax was bolled; but the wheat and the rye were not smitten, for they were not come up." Commentators agree that this event happened in the month of March; the first crop of barley was therefore nearly ripe, and the flax ready to pull: but the wheat and the rye sown in spring were not yet sufficiently advanced in growth to be injured by the hail.

Agricultural writers in general have distinguished the different species of barley, either from the time of sowing them, into winter barley and spring barley, or, from the numbers of rows of grains in the ears, into six-rowed, four-rowed, and two-rowed, or flat barley. Another distinction may be made, between those which have the corolla strongly adhering to the seed, and those in which it separates from it, leaving the seed naked, from which circumstance these are called *naked* barleys. Without entering into any discussion whether these differences are sufficient to constitute distinct species, or are to be considered as varieties produced by climate, soil, or cultivation, we shall only observe that those kinds which are hardier, and will bear the winters of our climate, may also with success be sown in spring, as is the case with the Scotch bere or bigg. There seem, in fact, to be only two very distinct species of barley generally cultivated: one which produces three perfect flowers, and as many seeds united at the base, at each joint of the *rachis*, or middle of the ear, alternately on each side (*fig.* 1), and another, in which the middle floret is perfect, and the two others barren, forming a flat ear, with only one row of grains on each side, as our common spring barley (*fig.* 2). The first species

d The three perfect grains adhering together by the base, as pulled off the rachis.

has sometimes the middle floret small or abortive, and consequently only four rows of grains, giving the ear a square appearance; but that this is only an occasional deviation is proved by its returning to the perfect ear with six rows, in rich soils, and under proper cultivation.

In some varieties of both kinds the seeds stand more apart from each other, and at a greater angle with the rachis; the ear is also shorter, giving it the appearance of a bat or fan, whence it has been called Battledore Barley; it is also known by the name of Sprat Barley. In others the corolla separates from the seed when ripe, and the awns fall off: these are the naked barleys. Each of these has been in repute at different times, and is worthy of the attention and careful cultivation of the practical and experimental agriculturist.

Winter barley is mostly sown in those countries where the winters are mild, and the springs dry, as in the south of France, Italy, and Spain, or in those where the snow lies deep all the winter, and where the sun is powerful immediately after the melting of the snow in spring, as is the case in parts of Russia, Poland, and some parts of North America. In most climates, where the winter consists of alternate frosts and thaws, and the early part of spring is usually wet, as is the case in England, Scotland, and Ireland, the young barley is too apt to suffer from these vicissitudes, and the spring-sown barley gives the more certain prospect of a good crop: but the grain of the latter is seldom so heavy as that which has stood the winter, and, being harvested later, it interferes with the wheat harvest, which is an inconvenience.

The winter-sown barley is generally of the six-rowed sort, of which the bere or bigg is an inferior variety, though, being hardy, and of rapid growth, it is well suited to exposed situations and inferior soils. The *Siberian barley*, a variety of which, with naked seeds, has been highly extolled by foreign agricultural writers, especially by Thaer, under the name of *Hordeum cœleste*, seems to be a superior sort in rich soils, not only for its heavy and nutritious grain, in which particulars it is said to approach to the quality of rye, but also for its succulent

stems and leaves, which make it by far the best sort to sow for the purpose of green food for cattle and sheep, and, if fed off early, the roots will, in a rich soil, shoot out an abundance of fresh stems, and produce a good crop of grain at harvest.

The barley most commonly cultivated in England is that which has only two rows. It is almost universally sown in spring. The varieties produced by difference of soil and cultivation, as well as by seed occasionally brought from other countries, are innumerable; they have been divided by most agricultural writers into early and late sorts; but this is a distinction which is not very accurate. It is well known that hot gravelly soils bring any grain to perfection in less time than the stronger and colder soils, and that the produce acquires from the soil in which it grew a disposition to ripen earlier or later. This property it retains for a few seasons, by some modification of its vegetating power, to which, for want of a better name, that of *habit* may be given, being analogous to the alterations produced on living animals by habit. Thus seed sown repeatedly in a light dry soil becomes early ripe, and that sown on the heavy moist land late ripe, although originally the same. The early grain is always less heavy than the late; and from these circumstances the experienced cultivator of barley chooses his seed from such land as may modify the habit produced by his own, giving him a crop with as heavy a grain as his soil can produce, and within a convenient period.

The common, or Norfolk, spring barley, so called because it is the principal sort cultivated in that county, has a moderate-sized ear, containing from ten to fifteen seeds on each side, on an average (*fig.* 2). The straw is not very long, and makes good fodder for cattle in winter. Some prefer the long-eared, which contains from twelve to twenty seeds in a row, but it has a weaker straw, and is subject to be beaten down by rains from the weight of the ear. Particular varieties have been in great repute at different times, when first introduced, and then seem to have degenerated and lost their superiority. Of this kind is the *Moldavian* barley. This barley was much sought after some years ago; and of late years the *Chevalier* barley (*fig.* 3), so called from the gentleman who first brought it into notice. It is said, that having observed an ear of barley in his field greatly superior to the rest, he carefully saved the seed, and cultivated it in his garden, till he had a sufficient quantity to sow it in a field. It has since been extremely multiplied and diffused through the country. Some eminent maltsters and brewers have declared, that it contains more saccharine matter than any other sort; and the trials hitherto made have convinced many agriculturists that it is not only heavier in the grain, but also more productive. In 1832 Mr. Coke, of Norfolk, who was always foremost in all agricultural experiments and improvements, sowed a con-

Fig. 3.

Chevalier Barley.

siderable portion of land with this barley, and the result is said to have been perfectly satisfactory. In the year 1833 the writer of this article sowed two acres of Chevalier barley in the same field with some of the best of the common barley. The soil was poor light sand, but in good order, and very clean. The produce of the whole was nearly the same, four quarters per acre; but the Chevalier barley weighed 57 lbs. per bushel, while the common weighed only 52. This gives the farmer an advantage of nearly ten per cent. The sample was very fine, and the whole that he could spare was eagerly purchased by his neighbours for seed at his own price. It is long in the ear and very plump, and the plants tiller* so much, that half a bushel may be saved per acre in the seed. This is probably owing to its grains being all perfect, and vegetating rapidly. The straw, like that of the other long-eared barleys, appears weak in proportion to the ear; it is said also to be harder, and not so palatable to cattle. These are circumstances which experience alone can ascertain. That hitherto it has a decided superiority over the common sorts, no one who has tried it fairly in well-prepared land seems to deny; but unless great care be taken in cultivating picked parcels for seed, selecting the finest ears and plumpest grain, it will probably share the fate of its predecessors—degenerate, and lose its reputation. This contingency, though anticipated many years ago, has not, however, yet (1859) befallen the Chevalier barley: it is still held to be among the best varieties we possess. There are many additional sorts of two-rowed barley deserving the attention of growers, under the different circumstances of soil and climate in which this grain is cultivated, as the Dunlop, the Annat, the so-called Italian; and other varieties might be named. The Annat barley and Italian are good, stiff strawed sorts, standing well where other kinds would be laid; the Dunlop is an early kind. A black, two-rowed barley, later than the kinds just named, but, in the instances in which we have known it tried, remarkable for its good malting quality, may also be named. There is also a black, six-rowed barley not however of greater merit for late cold climates than the hardy bere commonly grown in Ireland and the highlands of Scotland.

The Sprat, or Battledore, Barley (*fig.* 4), also called Putney Barley, from having been once extensively cultivated near that place, is in much esteem in Germany. It is the *Hordeum Zeocriton*; also called *German rice*, or *rice barley*, not from any resemblance it bears to rice,

* A plant is said to *tiller* when it produces several stems from the crown of the root (*fig.* 5, *a*) at the surface of the soil.

but because, when deprived of its skin and made into pot barley, it swells by boiling, and makes a good substitute for rice in broths and

Fig. 4.

Sprat (or Battledore) Barley.

puddings. It is not much cultivated in England at present, but it is hardy and productive, and grows well in stronger soils, especially the marly, and is well worth the attention of experimental agriculturists. It certainly was once in good repute in this country, and may suit particular soils and situations.

Might not the cultivation of the various kinds of grain purposely for seed be more generally practised, and form a distinct branch of agriculture? And would not this be well adapted to small occupiers and cottagers, who may have had allotments of land given or let to them, to enable them to live by their own labour and industry, without parochial aid? Thus the good qualities of any grain might be perpetuated, new varieties might be produced, and the defects corrected by cultivation, as is the case with horticultural plants.

All kinds of barley require nearly the same soil, and whether they are sown before winter or in spring, the ground must be well prepared, and the soil pulverised by repeated ploughings and harrowings, or by the operation of those instruments which have been invented for this especial purpose; in order that the fibres of the roots, which are very minute and delicate, may penetrate the soil easily in search of nourishment.

The cultivation of all the varieties is nearly the same, and is best understood in the counties of Essex, Norfolk, and Suffolk, in which a great quantity of excellent barley is produced and malted for the London market. In the light soils, barley is invariably sown after turnips, which have been fed off the land by sheep, or been drawn to feed the cattle in winter in the yards or stalls, which, by means of an abundance of litter, make a vast supply of manure ready for the next turnip crop. When the land has been properly prepared for turnips [TURNIPS], and well manured, and the turnips have been carefully hoed, so that no weeds of any kind remain, it is then in the finest state for barley as soon as the turnips are off. Turnips require a well-pulverised soil, and so does barley. If the soil is very dry and light, the sheep folded upon it consolidate the surface by their treading, and enrich it by their urine and dung. As soon as a part of the field is cleared and the hurdles removed, the land is ploughed with a shallow furrow, and thus the sheep and the ploughs are often seen in the same field succeeding each other, that no time may be lost in turning in and covering the dung, which is very volatile, and would soon lose much of its qualities by the action of the sun and winds. This is sufficient preparation for the seed, which may now be sown or drilled without delay.

In heavier soils, which have become tenacious by the winter's rains, or on which the sheep have been folded in wet weather, the soil may not be in a sufficiently divided state to receive the seed with advantage. In that case it must be worked and stirred till a proper tilth is produced: this is a great loss and hindrance, by increasing the labour at the busy time of sowing, but it cannot be avoided; the experience and judgment of the cultivator must direct him as to the best mode of proceeding, ever bearing in mind that it is an irretrievable error to sow barley on land not properly pulverised, and that, if it is once fine and dry, a little delay in the sowing is of much less importance. It can scarcely be too dry on the surface at the time of sowing, at least in this climate; and, provided a few showers supply the moisture necessary to make it vegetate and spring up, there is no great danger to be apprehended from too dry weather. Barley has been known to grow and ripen, when not a single shower refreshed the soil from the day it was sown to that in which it was reaped.

When the soil is of a strong, compact nature, but fertile, and turnips cannot be well fed off the land, nor taken off in carts, on account of the damage which would be done to the soft moist soil in winter, by the tread of the sheep, or the wheels of the carts, recourse is sometimes had to a *long fallow* during eighteen months, from harvest till the second spring, giving the land the benefit of two winters' frosts, a tillage in autumn, in summer, and in two springs. Thus the land is perfectly cleaned, and, if properly managed, quite mellow and fine; and the barley sown on such land always produces a crop, not only abundant, but of the best quality; so that the lines of Virgil in his 'Georgics,' i. 48, whether literally applicable or not, are verified in the result:—

> "Illa seges demum votis respondet avari
> Agricolæ, bis quæ solem, bis frigora sensit."

This practice has been alluded to in the article Arable Land, and is common in the heavier soils of Essex and Suffolk. The loss of time by so long a fallow is amply repaid by the state of the land and the subsequent crops. It was once the universal custom to sow wheat after a fallow, and barley after wheat, unless clover was sown with the wheat, which was the first step to improvement; but after the barley another fallow became necessary. By sowing barley after the fallow, the land is much more perfectly cleaned, and the clover sown with the barley is the best preparation for the wheat, which may be succeeded by beans, and if these are well manured and properly hoed, another crop of wheat may be taken before a second fallow is necessary. By comparing the probable produce of the two different rotations, the advantage will be evident in favour of that which begins with barley.

Fig. 5. Fig. 5.*

5. A root of self-sown barley in a rich light soil.
5* The same in a poor stiff soil.

In some particular cases, however, when a very dry autumn allows the wheat stubble to be ploughed and well cleaned before winter, and several ploughings and harrowings can be given in spring, barley may be sown with advantage after wheat; but then it is seldom advisable to sow clover and grass seeds with the barley, the land not being sufficiently free from weeds. But the *Trifolium incarnatum*, lately introduced from the south of France, which succeeds well in our climate, would be admirably adapted to be sown on the barley stubble: the land being slightly ploughed or scarified immediately after harvest, and the seed rolled in. It will grow so rapidly in spring as to smother all seed weeds, and will give a heavy green crop to be cut for horses and cattle early in May, and excellent winter fodder if made into hay. [Trifolium in Nat. Hist. Div.; Clover.]

The quantity of barley sown formerly was four or five bushels per acre: but, if the land is duly prepared and the seed good, from two to three bushels is an ample allowance, especially if sown by the drilling machine, which it always ought to be; for if the land be too rough to allow of drilling, it is scarcely fit to sow barley in, and oats will be a more advantageous grain.

The proper time for sowing barley depends much on the season and the state of the land. The best practical rule is, to sow as soon in March as the ground is dry. Earlier sowings may sometimes succeed well, but in this climate cold wet weather often prevails in the end of February, and this is by no means favourable to young plants of barley. The early-sown crops are, however, in general the heaviest, especially of the sort which ripen later: they require less seed, having more time to tiller before the hot weather draws up the stems. There are, however, seasons when the later-sown crops are the best: a good rule is, to sow a quick-growing sort when the sowing is unavoidably deferred, and in this case more seed must also be allowed.

The depth at which the seed should be deposited depends on the nature of the soil and on the season. Winter barley need only be slightly covered, and will tiller astonishingly in good light soils. The examination of two roots, one of which (*fig.* 5) proceeded from a grain dropped on the surface of the soil, and the other (*fig.* 6) buried one or two inches under the surface, clearly shows the difference. In the first, the crown (*a*), from which the stems tiller, has the seed still adhering to it; in the other, they are separated by a strong tough ligament (*c*). This forms two distinct centres, from which the roots spread; and, in very light soils and dry seasons, the roots, springing immediately from the seed, are less exposed to be dried up. But in stiff soils the seed buried deep may have much difficulty in germinating, the air not having sufficient access, and the first shoot, which forms the ligament (*c*), not being able to pierce the compact soil above

Fig. 6. Fig. 6.*

6. A root of barley in a good soil.
6*. The same in a poor soil.

it. As a general rule, a depth of from 1½ to 3 inches, according to the nature of the soil, is most likely to enable the seed to sprout well, and give a sufficient hold of the land by the roots to avoid the danger of lodging. It is of consequence that all the seeds be deposited at a uniform depth, to ensure their shoots rising at the same time: for where some rise earlier and some later, it is impossible to reap the whole in good order; some of the ears will be too green, while others are shedding the seed from being too ripe. This is one reason why the drilled crops are, in general, so much more regular in their growth than the broadcast. After sowing barley, it is useful to pass a light roller over the land, across the ridges, if there are any, to press the earth on the seed, and prevent too great evaporation of the moisture. When the plants begin to tiller, another rolling, and in some cases a slight harrowing, to loosen the surface and thin out the plants where they grow too close, is very useful. This also is the best time to sow clover and grass seeds, if not done with the first rolling. Barley is not usually hoed, because the land should be perfectly clear of weeds and their seeds, before it is sown, and because clover and grass seeds are usually sown either with the barley or immediately after it; but if hoeing is thought necessary to loosen the soil, instead of merely harrowing it, the clover or grass seeds are sown at the last hoeing. After this no attention is required to the crop till harvest, unless docks or thistles should make their appearance, which must then be carefully pulled up.

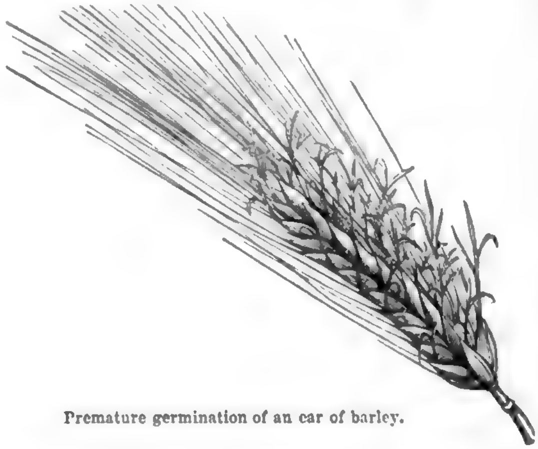
The practice of sowing clover, rye grass, or other seeds, with the barley, is almost universal, and is considered as one of the great modern improvements in agriculture. There is no doubt a great advantage in having a profitable and improving crop to succeed the barley, without further tillage; and clover prepares the land admirably for wheat. Still there are some doubts whether this be profitable in all cases. There are seasons when the clover materially injures the barley by its luxuriance; and, in wet seasons at harvest, it is very difficult to dry the straw sufficiently, mixed as it is with the succulent stems of the clover, or to prevent its heating in the stack. The clover, as far as the barley is concerned, may be looked upon as a weed, which, like all other weeds, must take a part of the nourishment from the crop, and check its tillering. If the clover is sown late among the barley, the danger is less. It will not be able to grow so high as to do much injury, but the fear of losing the plant of clover makes most farmers prefer sowing it soon after the barley.

In Flanders, clover is seldom, or never, sown with barley, but chiefly with rye: but they sow a species of white carrot instead, in the sandy soils. These push out very little of the green top, but shoot their fibres downwards, which form the rudiments of the carrot. After harvest, the ground is well harrowed, and watered with liquid manure. The carrots, which could scarcely be observed above ground, soon spring up, and a good crop is secured before winter, extremely useful for feeding cattle and swine, and greatly increasing the urine of cows and bullocks, the favourite manure for light soils in that country.

As soon as the ears of the barley droop, it should be reaped. In the case of wheat it is well to reap before the grain has fully hardened in the ear—for the last stage in the process of ripening converts a portion of the farinaceous contents of the seed into a woody husk, comparatively useless as food. The quantity of bran in a fully ripened grain of wheat is greater than if it had been harvested earlier. In the case of oats again, it is generally well to reap even before the green hue of the crop has entirely gone, for if the plant be allowed thoroughly to dry and ripen standing, the seeds will be extremely liable to be shaken out by wind. In barley, on the other hand, which has to be converted into malt, the quality of which depends on the germinating process being carried on uniformly throughout the mass, it is necessary that the grain be all of one uniform stage of ripeness when cut, and this is generally only to be ensured by taking care that it be all dead ripe. When therefore the ears have all turned down, it may be reaped. This is usually done by mowing it with a scythe, having a hoop, or an appendage called a *cradle*, fixed to it, so as to lay the swathe regularly. The *Haynault scythe*, a short, broad scythe used with one hand, while a light hook is held in the other to lay the straw even, so as to be readily tied up into sheaves, is another good tool; and the heavy "bagging" hook is often used for the same purpose; but the horse-drawn reaping machine is now rapidly gaining its way, and will no doubt soon, to a great extent, supersede manual labour, so far as the mere cutting is concerned. [HARVEST.] Binding into sheaves is a great advantage: much less corn is shed, which, in the common method of raking into heaps, often amounts to more than would fully sow the same extent of land. The sheaves set up on end are in less danger from the weather, and when the stack is built, all the ears may be laid inward and much grain saved, which, if on the outside, would soon be the prey of birds: smaller stacks may be made, and the danger of heating entirely avoided. The stacks should be built on frames, supported by stone or cast-iron pillars, with flat caps on them to keep out vermin; and, in large stacks, it is useful to have a kind of open cage in the middle, to allow the admission of air to the centre. This dries the grain better than a kiln, and when the stack is properly thatched with straw, the crop may be considered as safe till it is carried into the barn to be thrashed. [HARVEST; FARM.]

In thrashing barley, an extra process has to be adopted in order to break off all the awns close to the grain. A thrashing machine does not accomplish this perfectly by only once passing the straw through the rollers; it is consequently usually put through a second time, especially if it has not been tied into sheaves. But it is generally necessary, after the barley is thrashed, to effect this by another operation, which is called *hummeling*, for which purpose several different kinds of instruments are used. A simple one consists of a cylinder composed of small bars of iron, and placed on an axis, which is rolled backwards and forwards over the grain; or, where a thrashing machine is used, a plate of iron, perforated like a nutmeg-grater, is fixed to the inside of the drum in which the beaters revolve, and the awns are effectually broken off by this rough surface. This process is, however, more generally now effected by an addition to the thrashing machine, through which all the grain when separated from the straw is passed, coming under the action of rapidly revolving knives, which break the brittle awn into dust, to be afterwards separated by the blast and riddles of the winnower.

The diseases to which barley is subject while growing are those which attack all other grain—the smut, the burnt ear, blight, and mildew; but it is less liable to these than wheat. The greatest enemy is a wet harvest. It is so apt to germinate with the least continuance of moisture, that even before it is reaped, it often exhibits an ear in full vegetation, every grain having sprouted (see *fig.*). It is then of little



Premature germination of an ear of barley.

value, and even when this is checked by dry weather or in the kiln, the grain is so impaired as to be fit only to feed fowls and pigs. A strong plant of clover, by keeping the wet longer about the barley, often contributes to increase this evil, as has been hinted before.

The principal use of barley in this country, and wherever the climate does not permit the vine to thrive, and no wine is made, is to convert it into malt for brewing and distilling. [MALT.] The best and heaviest grain is chosen for this purpose, and, as it must have its germinating power unimpaired, the least discoloration, from rain or heating in the stack, renders it suspected, and consequently not so saleable. It is, however, still fit for being ground into meal, for feeding cattle and pigs, when it is not used for human food; or it may be made into pot-barley by the process of shelling. [BARLEY, POT and PEARL.]

The produce of barley, on land well prepared, is from 30 to 50 bushels, and more, per statute acre, weighing from 45 to 55 lbs. per bushel, according to the quality.

On all good loamy soils barley is a more profitable crop than oats, and is supposed to exhaust the soil less, and of late years (1857-8) the extraordinary prices it has reached have rendered it more profitable than even wheat. On stiff cold clays it does not thrive so well, and there oats are to be preferred. In some districts, where the best barley is grown, the farmers seldom sow oats, and many prefer buying them for their own use, with the additional expense of market and carriage. In Scotland, and some parts of the north of England, oats are in greater request, being the chief food of the labouring classes, and preferred by them to barley, except it be in the form of pot-barley in their broth.

Barley in its green state, especially the Siberian winter barley, makes excellent spring food for milch cows, as is well known to the cow-keepers about London; it comes in early, and greatly increases the milk. It is also very good for horses, provided it be given sparingly at first, as it purges them; but after a little time, when the stomach becomes accustomed to it, it increases their flesh and condition wonderfully, and is much more wholesome than the usual spring physic, as it answers the purpose of gently clearing the intestines, without any risk of irritation. For sheep it is more nourishing than rye, and comes earlier: when fed off quite close in April, it will spring up again, and, on good land, produce a fair crop of grain in August, but in general it is ploughed up as soon as it is fed off, and succeeded by spring tares or turnips.

Barley has always been considered as possessing medicinal virtues; decoctions of it have long been used for the sick, especially in all pulmonary complaints; and with the addition of some vegetable acid, it is extremely grateful in fevers, allaying thirst, and giving such a degree of nourishment as is indispensable, without exciting the circulation.

Professor Johnston gives the composition of barley-meal as follows :—

Water	14 per cent.
Gluten	14 „
Starch	68 „
Fatty matter	2 „
Ash	2 „
	100

The whole grain, according to Mr. Horsford's analysis, contains 15·3 per cent. of gluten and other nitrogenous compounds. Dr. Playfair, in Morton's 'Cyclopædia of Agriculture,' puts it as follows :—

Nitrogenous substances	13 per cent.
Starch	56 „
Woody fibre	13½ „
Ash	3½ „
Water	14 „
	100

A crop of 36 bushels on about 1½ tons of straw from each acre, will contain,—according to Dr. Playfair's statement, as follows :—

	In the Grain. lbs.	In the Straw. lbs.	In both. lbs.
Nitrogenous matter	243	62	305
Starch and fibre	1301	2987	4288
Ash	66	191	257
Water	262	398	660
	1872	3638	5510

The ash contains the following ingredients :—

	Of the Grain.	Of the Straw.
Potash	15·61	22·17
Soda	5·03	0·84
Lime	3·06	7·59
Magnesia	8·04	3·55
Iron and loss	1·24	4·35 (?)
Phosphoric acid	35·68	3·22
Sulphuric acid	1·22	2·61
Silica	28·97	46·30
Chloride of sodium	0·45	9·37

These are Dr. Playfair's figures: they agree pretty accurately with those of Messrs. Way and Ogsten, as given in the Journal of the English Agricultural Society. The remarkable feature in these analyses, as compared with those of wheat and oats, is the presence of so large a percentage of magnesia. The quantity of silica in the ash of the grain of barley, is due to the chaff or husk of the floret, which in barley adheres to the grain. The ash of naked barley would more nearly resemble that of other grains.

In the three years ending with 1858, the quantity of foreign barley imported amounted on an average to 1,398,000 quarters annually.

BARLEY, POT and PEARL. Pot-barley is barley of which the outer skin only has been removed; whereas pearl-barley is the small round kernel which remains after the skin and a considerable portion of the barley have been ground off.

Both these preparations of barley are made by means of mills constructed for the purpose, and differ only in the degree of grinding which the grain undergoes.

There are two kinds of mills for making pot and pearl barley. The mill which was probably the earliest in use, and which is still common in parts of Germany and France, to take off the husk of the barley, is similar to a common flour-mill, having two millstones, of which one is fixed and the other revolves horizontally over it; but these stones are of less diameters than common millstones, not exceeding three feet each. The upper stone has six grooves, in the form of the fourth part of a circle, cut in the lower surface from the centre to the circum-

Fig. 1.

ference; the width and depth of these grooves increase from one inch in the centre to two inches at the circumference (see *fig.* 1). This stone has a perforation in the centre, as a common upper millstone, and revolves on a vertical axis or spindle of iron, the lower point of which moves in a metal cup fixed on an elastic horizontal beam. It is absolutely requisite that this axis be perfectly vertical, and the stones accurately horizontal, in order that the upper stone may move parallel to the lower, at such a distance as to rub the grain without crushing it. The mill is fed by a hopper through the central aperture, as in the common corn mill. The stones are surrounded by a circular case, leaving a space of from two to three inches between the circumferences. The top or flat part of this case is of wood, and has an aperture corresponding with the central aperture of the upper stone; but the circumference consists of thin plates of iron perforated from the outside, by means of a flat punch, with holes, as near each other as possible, making the inside of the case rough, like a nutmeg-grater. A square opening in this case, with a sliding door over it, serves to let out the barley after it has been sufficiently ground. In order to loosen the skin without rendering the substance of the grain too soft, the barley, which is chosen dry and hard, is sprinkled with water on the floor, and turned over two or three times in the course of eight or ten hours: it is then fit to be put into the mill. The upper stone is made to revolve from 200 to 300 times in a minute. The barley, gradually supplied from the hopper, is carried round in the grooves of the upper stone and rubbed on the under without being broken. The centrifugal force and the strong current of air produced by the grooves and the rapid motion, drive the grain, partially ground, against the rough case, and complete the removal of every part of the skin. The rubbed grain is then let out through the square opening, and falls on a sieve, which separates the naked grain from the bran. This is pot-barley. To make pearl-barley, the operation is continued till the required degree of fineness is produced. As the greater part of the finer particles of the barley ground off escape through the holes in the case, it is surrounded by another to collect this meal, or a cloth is fixed all round, which lets it fall gently in a bin below; thus nothing is lost. This meal is excellent food for cattle, pigs, or poultry. The chief objection to mills of this construction is, that they require great nicety in the adjustment of the stones, and are very apt to waste the barley by grinding it unequally, and that, at all events, the larger grains are more ground than the smaller; but for pearl-barley, which ought to be of a uniform size, this is rather an advantage. But, on the other hand, the process goes on without interruption, and if two or more pairs of stones are placed under each other, the barley may pass from the first into the hopper of a second, and from this into a third, so as to come out of the last of any required degree of fineness. It may be observed, that the

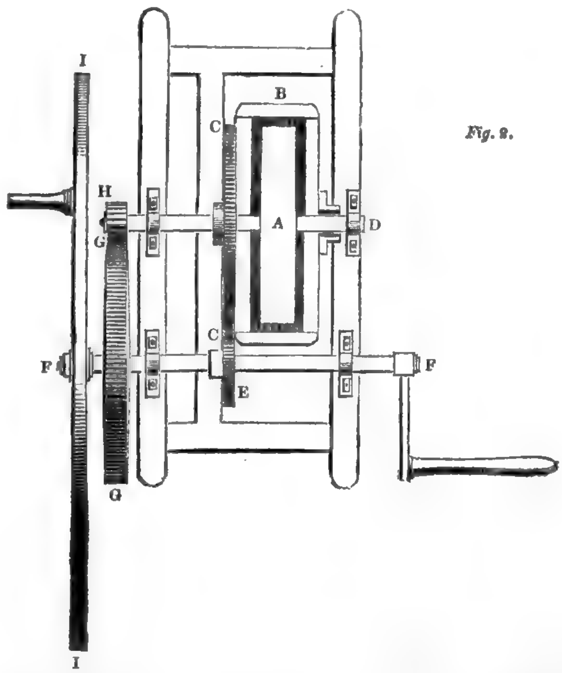


Fig. 2.

The construction of this machine may be thus briefly described: A, section of the stone turned by the axis D. B, section of the case which turns on the axis D, by means of brass bushes in its centre. C C, a wheel having sixty teeth, or cogs, fixed to the side of the case. C E, a smaller wheel, or pinion, with fifteen teeth, moving the wheel C C, and fixed on the axis F F, by which the whole is moved. G G, a wheel with sixty teeth, on the axis F F, moving the pinion G H, which has twelve teeth, with the axis D, which carries the stone. I I, a fly-wheel, which equalises the motion of the whole.

principal use of the upper stone and its grooves is to carry the barley round and throw it against the case, and therefore any hard wood with similar grooves, will answer the purpose as well as stone; and this is said to be the construction of several of these mills.

The other kind of mill is in general use in Scotland, where most of the pot and pearl-barley used in this country are prepared. It was originally introduced from Holland, whence formerly all Europe was once supplied with pearl-barley, commonly called Dutch pearl-barley. This mill consists of a common grindstone such as cutlers use, about three feet in diameter, revolving vertically on a horizontal axis. A case, similar to the one already described, revolves on the same axis, and in the same direction, with a slower motion. Sometimes flat, the sides of this case, as well as the rim or circumference, are composed of perforated plates of iron; but this is not absolutely necessary. The barley, prepared as before, is put in by a square opening in the circumference, the slide shut, and the machinery is set in motion, until the barley, tossed between the stone and the case by the double motion, has been entirely deprived of its skin, and is become pot-barley; or till it is ground into the small round shape of pearl-barley. The mill is then stopped, the slide pulled out, and the case being turned so as to have the opening undermost, the prepared barley falls out into the bag or bin placed to receive it. The grain scarcely wants any sifting; for such is the violence with which it has been tossed about, that all that is ground off is driven through the holes in the case, and is collected in a close chamber which surrounds the apparatus, as in the other mill. The mechanism by which the motions of the stone and case are produced, is extremely simple, and will be easily understood by reference to a figure, which, although taken from a portable hand-mill for making pearl-barley, is on the same principle as the larger.

By this combination of wheel-work, if the handle turns once in a second, the case turns fifteen times in a minute, and the stone 300 times. This is the usual velocity in large mills. A hand-mill may be moved with one-half or two-thirds of this velocity, the stone being also smaller. When the power is sufficient to turn a stone three feet in diameter 300 times in a minute, three bushels of barley may be converted into pot-barley in an hour, and into pearl-barley in two hours.

The advantages of the mill shown in the next figure are considerable. It requires no very nice adjustment, and is not easily put out of order. The stone may continue in use, although considerably worn down, even to half its original diameter. There is no danger of crushing any of the grains, nor much waste; and whatever be the size of the grains, it grinds them equally. If the pearl-barley is required very equal in size, it may easily be sorted by wire sieves. The only defect of this construction is the loss of time and of power which it occasions, by the case being stopped to take out the prepared grain, and replace it by fresh barley. Ingenuity will probably find means of removing this defect; but we are not aware of any late improvements in the construction of these mills.

Pot and pearl-barley are very wholesome and nutritious, and have a more agreeable taste than barley-meal; and it is to be regretted that they are not more used as food by the labouring classes in England, as

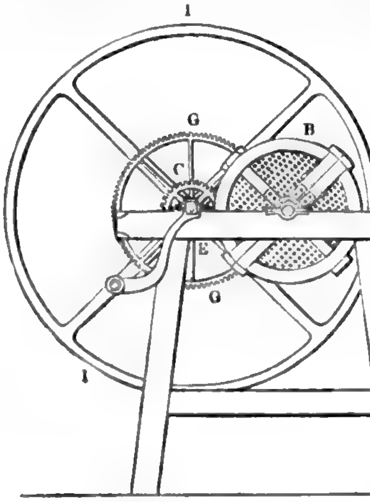

Fig. 3.

[Hand Barley Mill, with the perforated plates on the case.]

they are in Scotland, Germany, and Holland. The essential oil of barley, which gives it its peculiar taste, resides chiefly in the skin and adjacent parts of the grain; the interior is a purer farina, more nearly resembling that of wheat. This has probably suggested the idea of removing these outer parts, as less palatable, and given rise to the manufacture of pearl-barley, the farina of which approaches nearer to pure fecula, or starch. This farina, obtained by grinding pearl-barley in a common mill, is sold under the name of patent barley, and is used extensively for readily making barley-water for the sick. But if the essential oil of barley possesses any medicinal properties, it is evident, from what was observed before, that common pot-barley would be preferable for making a decoction of barley when prescribed as a remedy. The great use of pot and pearl-barley is in broths, stews, and puddings, as a substitute for rice. It swells, and has the property of uniting well with the fat and oily matters extracted from meat in boiling. Barley-broth is a constant and principal dish at every family dinner among the middling ranks in Scotland, and not despised by the higher. Even the bran, having been steeped in water, and allowed to ferment till it becomes acid, is relished by the lower orders in the mess called *sowens*. In Holland, pot-barley, boiled in butter-milk and sweetened with treacle, is a common food for children and servants.

BARLEY-BREAK, a popular pastime of the reign of James I., allusions to which repeatedly occur in our old writers. It was played by six people, three of each sex, who were coupled by lot. A piece of ground was then chosen and divided into three compartments, of which the middle one was called hell. It was the object of the couple condemned to this division, to catch the others who advanced from the two extremities; in which case a change of situation took place, and hell was filled by the couple who were excluded, by pre-occupation, from the other places. In this "catching," however, there was some difficulty, as, by the regulations of the game, the middle couple were not to separate before they had succeeded, while the others might break hands whenever they found themselves hard pressed. When all had been taken in turn, the last couple was said *to be in hell*, and the game ended.

Several poetical descriptions of this amusement are extant: one in 'Barley-breake, or a Warning for Wantons,' written by W. N. Gent., 4to, Lond. 1607; another in Sir Philip Sydney's 'Arcadia;' and a third in Sir John Suckling's 'Poems,' the two last of which have been quoted by Brand in his account of Barley-break, 'Popular Antiquities,' vol. ii.; see also Gifford's 'Notes' to his edition of Massinger, who has frequent allusions to Barley-break.

Dr. Jamieson, in his 'Etymological Dictionary of the Scottish Language,' gives an account of this game as it is still played in the north of Scotland. He calls it "a game generally played by young people in a corn-yard; hence called 'Barla-bracks about the stacks.' One stack is fixed on as the dule or goal; and one person is appointed to catch the rest of the company, who run out from the dule. He does not leave it till they are all out of his sight. Then he sets off to catch them. Any one who is taken, cannot run out again with his former associates, being accounted a prisoner, but is obliged to assist his captor in pursuing the rest. When all are taken, the game is finished; and he who was first taken, is bound to act as catcher in the next game." He adds, "This innocent sport seems to be almost entirely forgotten in the south of Scotland; it is also falling into desuetude in the north."

Nares, in his 'Glossary,' 4to, Lond. 1822, says, our very puerile game of *tag* seems to be derived from barley-break; there was a tig or tag in the Yorkshire game of barley-break, as played within memory; the touch of the person called tig or tag made a prisoner.

BARM. [YEAST.]

BARN. [HOMESTEAD.]

BARO'METER, from two Greek words, *βάρος*, weight, and *μέτρον*, a measure, or *the measurer of weight*, a term generally applied to those instruments in which a column of air is weighed against a column of mercury.

The invention of the barometer is one of the most curious in the history of philosophy. No new discoveries, not even those first substantiated by the telescope, ever knocked so hard at the door of a received system, or in a manner which so imperiously demanded admission, as this one. It will therefore be worth while to state the circumstances attending it.

The phenomena of the common pump had been well known for more than a century at least before the commencement of the Christian era. The mode of explaining them was simply by means of the well-known maxim, that "nature abhors a vacuum." Nor do we know of any experimental attempt to discover why nature abhorred a vacuum before the time of Galileo. The phrase itself, considered simply as a representation of a well-known fact—namely, that the laws of nature will not permit a vacuum to exist—may be as useful now as then. But considered as an explanation, we need not dwell upon its utter worthlessness. We might equally well explain how a stone falls 16 feet 1 inch in the first second of its descent by saying that its nature has an antipathy to more, and a repugnance (if we wish to vary the phrase) to less.

Very general terms, such as *vacuum*, *space*, &c., furnish no tests of the validity of a method of explanation, when compared with others which have direct numerical meaning. The common story is, that the pump-makers of the Duke of Florence found that water would not rise in the pipe of the pump higher than 32 feet, or thereabouts, when the air was exhausted from it. They applied to Galileo for a solution of this problem, and he, having his mind pre-occupied by the usual form of words, gave them a very simple answer, namely, that the power of nature to contend against a vacuum ceased when she had destroyed one of 32 feet high. [GALILEO, BIOG. DIV.] That the mysterious indefinite *nature* should be in constant hostility to the equally mysterious indefinite *vacuum*, would not then appear ludicrous; but *thirty-two feet* must have destroyed all the poetry of the explanation, and it had nothing else to depend upon. The above story is told in several different ways (it has been said, for instance, that the answer of Galileo was ironical), but whichever may be true, it is most probable that it led him to abandon the theory of nature's horror, though without substituting any other. It has been thought that before his death he suspected at least the true explanation. His pupil Torricelli first imagined that the weight of the atmosphere might be the counterpoise to the 32 feet of water; or at least he was the first whom we know to have applied himself to try this hypothesis by experiment. He saw that, if it be a weight of air which counterpoises the 32 feet of water, it must follow that by the substitution of mercury instead of water, the height of the column necessary to counterpoise the weight of air would be reduced in the proportion in which mercury is heavier than water. For instance, that if mercury be fourteen times heavier than water, bulk for bulk, the fourteenth part of 32 feet, or about 2 feet 4 inches, would supply the place and produce the effect of the water. He accordingly filled a tube, more than 3 feet long, and open at one end only, with mercury; and then stopping the open end with the finger, he placed the tube in an open vessel of mercury with the open end downwards. On removing the finger, the mercury in the tube sank until it stood in the tube at about 28 inches higher than the mercury in the vessel. He thus constructed what is at this time considered the best form of the barometer.

Torricelli died shortly afterwards (1647), leaving his great discovery not quite complete; for though he had made it apparent that the weight of the water and of the mercury was a counterpoise of something, most probably of a weight of air, the latter was not quite certain. The invention however was taken up by Pascal, Mersenne, and others in France, and by Boyle in England. The latter, by means of the air-pump, was enabled to subject air of different degrees of density to the test of the barometer. Pascal did the same; and, in addition, first suggested (in 1647) that if the mercury were sustained by the weight of the air, it would necessarily fall in ascending a high mountain, by the diminution of the superincumbent column of air. He accordingly requested his relative, M. Perrier, to try the barometer at the summit and the base of the mountain of Puy de Dôme, in Auvergne, and the result was that the mercury, which at the base stood $26\frac{1}{2}$ inches (French), was only $23\frac{1}{6}$ inches at the summit. Pascal afterwards found the same result to be sensibly shown in the ascent of a church tower and of a private house. The fact was now completely established, that the weight of the air upon any horizontal base was equivalent, roughly speaking, to a weight of mercury of the same base, and about 28 inches high. The ancient philosophers might have come to a corresponding conclusion; for, as Deluc remarks, though they had not mercurial barometers, they had pumps, with which, had the taste for experimental inquiry existed, they might easily have performed Pascal's experiment. But the personification of nature answered every purpose, and checked every inquiry.

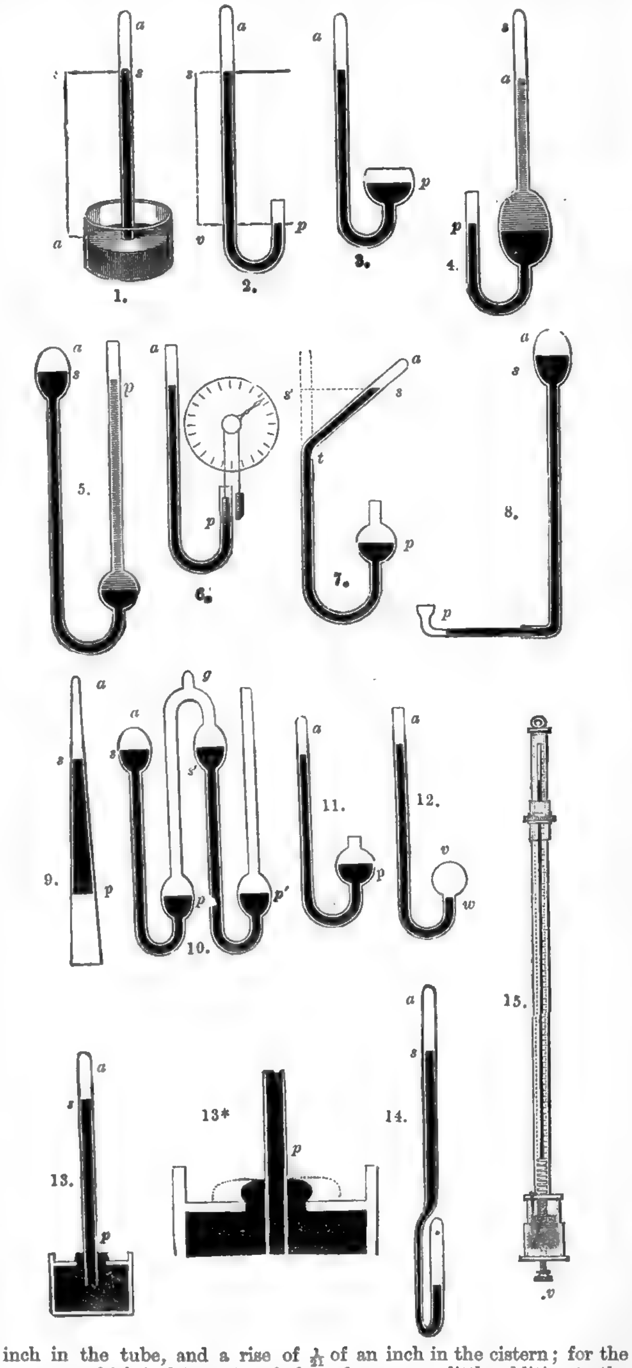
Soon after the first discovery of the barometer, many different methods were imagined for improving the construction of the instrument. The continual variations of the altitude of the mercury did not escape notice; and the idea of the *weather-glass* was almost contemporaneous with that of the *barometer*. It was observed, that changes in the height of the mercury corresponded to changes of the weather, though experience was not yet sufficiently extensive to decide in what manner. The very gradual progress of these changes, and the frequent smallness of their amount, rendered it desirable so to construct the instrument that the effect should be multiplied as much as possible. And since an alteration of level in the tube of the barometer also produces an alteration of level in the cistern with which it communicates, it soon became evident that no fixed scale of inches would serve to show the difference of levels (or, as it is called, *the height of the barometer*) merely by reading off the height of the mercury in the tube.

We shall now give an account of the most remarkable among the various constructions which have been employed or suggested. Most of them are from De Luc, 'Recherches sur les Modifications de l'Atmosphère.' In all the diagrams, *a* is the closed or vacuum end of the tube, and *p* the place where the mercurial or other column communicates directly with the atmosphere. The bulbs which are drawn as such should all, properly speaking, be cylinders. Enough is introduced to show the principle of the construction, but not the method of mounting the instrument. In the following descriptions each article is headed by the name of the inventor, or by that of the instrument.

Many of the following contrivances, though not at present in use, may suggest ideas of value for other purposes:—

1. *Torricelli.*—This is the simple apparatus already described. The inverted tube, full of mercury, 33 or 34 inches in length, is placed in the cistern of mercury. The fluid sinks until the column contained between the two levels counterbalances the pressure of the air. From *a* to *s* there is a vacuum, named, in honour of the inventor of the instrument, *the Torricellian vacuum*, or at least a space only filled with the *vapour of mercury*, which we shall presently mention.

2 and 3.—The *siphon* barometer, No. 2, was early adopted as a more convenient form than that of Torricelli. The pressure of the air at *p* is counterbalanced by a column of mercury in length *s v*. But the indications of this barometer are not nearly so great as those of Torricelli's; for an inch of variation in the difference of levels makes the mercury in the closed tube descend half an inch, and that in the open tube ascend half an inch, or *vice versâ*; thus altering *s v* by one inch (*s* falling half an inch, and *p* rising half an inch). In Torricelli's barometer, if the horizontal section of the cistern (the part occupied by the tube excluded) were twenty times that of the tube, then a diminution of an inch in *s v* would be marked by a fall of $\frac{20}{21}$ of an



inch in the tube, and a rise of $\frac{1}{21}$ of an inch in the cistern; for the mercury which is driven out of the tube causes a little addition to the cylinder of mercury in the cistern, of twenty times the base it occupied while in the tube, and therefore of only one-twentieth of its height. No. 3 is a siphon barometer, with a similar method of increasing the variation in the tube. The siphon terminates in a basin of greater diameter than the tube. If the horizontal section of the basin be twenty times that of the tube, we have again the case just explained.

4. *Descartes.*—Here we have the top of a barometer so constructed, that a narrow tube shall open into a wider cistern, which opens downwards into a tube. Any light fluid, say oil, is first poured in, and afterwards mercury; the vacuum is then made as in Torricelli's experiment, and the quantity of oil and the diameter of the cistern are so adjusted, that the extreme variations of the weight of the atmosphere shall allow some mercury to remain in the cistern. Let us say that the specific gravity of the oil is one-twentieth that of mercury, or that a column of oil is of the same weight as a column of mercury one-twentieth of its length; and let us suppose a fall of an inch in the purely mercurial barometer. Let us also suppose the horizontal section of the cylinder to be ten times that of the tube above and

below; then any descent of the mercury in the cylinder is shown by ten times as great a descent of the point s in the upper tube, because a portion of the cylinder must be filled out of the tube. When Torricelli's barometer falls an inch, the mercury here will fall $\frac{1}{2}$ of an inch, and the oil $\frac{13}{2}$, or $6\frac{1}{2}$ of an inch; this $\frac{13}{2}$ of an inch of oil being equivalent only to $\frac{1}{2}$ of an inch of mercury; and a fall of $\frac{1}{100}$ of an inch of Torricelli's barometer would be marked by a fall of $\frac{1}{16}$ of an inch in that of Descartes. Huyghens tried to construct this barometer (Descartes having died before he completed it), but found that the air contained in the upper fluid always escaped into the vacuum. He therefore suggested the next plan.

5. *Huyghens.*—To the siphon barometer he added a cistern at the vacuum end of the tube, equal in diameter to the cistern in which the mercury communicates with the air. The latter cistern communicates with a narrow tube, say one-tenth of the horizontal section of the cistern, and the barometer was completed with such a quantity of mercury as would always leave some in both cisterns. The remainder of the lower cistern, and a portion of the tube above it, were filled with water. Now it is evident, that the water is merely to be considered as a very small addition to the weight of the atmosphere. A depression of an inch in Torricelli's barometer would cause a depression of half an inch in the higher cistern, and a rise of half an inch in the lower. Neglecting the effect of the weight of the column of water, it appears that a rise of half an inch in the lower cistern would be accompanied by ten times as great a rise of the water in the tube, on account of the proportion of the horizontal sections. Hence the water multiplies the indications of Torricelli's barometer five times. The objections to this construction are: that the portion of the tube abandoned by the sinking of the water remains wet, or a part of the water is left behind, so that it appears to have descended somewhat lower than it ought to do; and also that the evaporation of the water produces a similar effect. We need hardly observe that, except for extreme exactness of observation, no improvement upon Torricelli's barometer is here pretended to have been made; so that, if this end be not answered, the whole peculiarities of the construction are useless. Dr. Hooke slightly varied this barometer, by adding another fluid above the first, and making the tube terminate in a third cistern.

6. *Hooke's* wheel barometer is a well-known plaything, for as to accuracy it scarcely deserves a better name. On the mercury in the siphon barometer a weight is placed, which is very nearly counterpoised over a pulley by another weight. The ascent of the mercury raises the weight, and the string which connects the weights makes the pulley revolve more or less. A hand attached to the pulley shows the quantity of revolution, and the plate is divided so as to show how much revolution of the pulley corresponds to a hundredth of an inch (usually) of rise or fall in the barometer. In the common instruments it is usual to mark *fair*, *changeable*, &c., at certain places; an innocent practice, because those who use the instrument are generally aware that it is not the *state* of the barometer which furnishes any probable test of the weather, but the *change* which is taking place for the time being. For observing the mere fact of a change, and roughly whether it is much or little, this instrument is sufficiently well adapted for those who wish to "give an air of philosophy to their parlours," but for marking the exact quantity of the change, or the absolute height of the column, it is worth very little.

7. *Sir Samuel Morland.*—By inclining the tube of the barometer its indications were supposed to be rendered more sensible. The mercury standing at s' in the upright barometer (dotted) would stand at s on the same level in the *oblique* or *diagonal* barometer, by a well-known law of hydrostatics; and since any difference of levels cuts off a longer space from an inclined, than from a vertical line, the indications of change on the former must be more marked than on the latter; but the friction of the mercury is increased, and the place of the head of the column of mercury is difficult to be read by a vertical scale, because of its inclination.

8. *John Bernoulli.*—The mercurial column is here made to end in a smaller horizontal tube of considerable length, the pressure of the air acting horizontally against the column of mercury. The vacuum is made in a cistern, as in No. 5. This, and the smallness of the horizontal tube, render the indications very great, in the manner already explained. There is no change in the lower level of the mercury; but other circumstances render this construction not more worthy of confidence than the preceding. An improved form of this instrument has lately been introduced by M. de Celles.

9. *Amontons.*—A conical tube of glass is closed at the upper end. It is partly filled with mercury, and the tube is inverted. The pressure of the air from underneath prevents the total descent of the mercury, but allows it to descend in the cone until it forms a column of a height sufficient to counterpoise the weight of the atmosphere. It is evident, that in a conical tube the column, as it descends, will spread horizontally and decrease in height. But by the laws of hydrostatics it is the vertical height of the column only on which depends the pressure per square inch on the base. If the weight of the air decrease, the mercury must fall until, by increase of its horizontal dimensions, the height has been decreased as much as is necessary. But a tube of the requisite degree of accuracy is almost an ideal supposition. The principle itself is the most simple and elegant of all those which have been applied to the instrument.

10. *Amontons.*—This is a barometer in which the column of external air is balanced by several different columns of mercury, as follows:—From a to s is a vacuum as usual; from s to p mercury; from p to s' air; from s' to p' mercury. When $a\,s\,p$ has been filled in the usual manner, the mercury $s'\,p'$ is admitted at g, which is then closed. Neglecting entirely the weight of the air $p\,s'$, and considering it merely as a medium for communicating pressure, the difference of levels of p and s, and of p' and s', will each be half of the column for the time being in the Torricellian barometer. For the pressure of the external air at p' is counterbalanced by the pressure of the two columns, that of the column beginning at s being communicated to that beginning at s' by the intermediate air $p\,s'$. By a repetition of the same principle, each column might be made one-third, one-fourth, &c., of the Torricellian column. But the exactness required in the several parts is impossible to be attained.

11. *Mairan.*—This is a simple siphon barometer, so short in the tube that the mercury does not descend until the density of the superincumbent air is considerably less than that of natural air. It is used under the receiver of an air-pump [AIR-PUMP] to indicate the degree of exhaustion which has taken place.

12. *Hooke.*—This barometer was intended to be used at sea. It is not a mercurial barometer, but a portion of air confined in the bulb $r\,w$ by the liquid which mounts in the tube. Any increase of weight in the exterior air compresses the air in the bulb by pressing on the liquid. This is not at all to be depended upon, as the effect of changes of temperature makes it rather more of the thermometer than the barometer.

13. *Prins.*—This is a Torricellian barometer, with a contrivance for keeping the lower level always the same. The cistern is closed at the top, excepting an orifice very little larger than is necessary to admit the tube. The mercury escaping through this orifice, and its cohesion, with the repulsion which it exercises towards glass, preventing any part separating from the rest, it forms a bulb round the tube, which bulb, when the mercury falls into the tube, instead of rising, spreads itself out upon the glass, in the manner shown in the dotted section. (*Fig.* 13*.)

14. *Gay Lussac.*—This barometer is very convenient for carriage. It is a siphon barometer, differing from others of that species only in form, and communicating with the external air through a hole g, pierced too small to allow mercury to pass through it.

15. *Fortin.*—This barometer is distinguished from the rest by a method of adjusting the lower level of the mercury exactly to the zero point of the scale before commencing the observation. It is a Torricellian barometer, in which the bottom of the cistern can be raised or lowered by a screw. An ivory needle points downwards, the point of which is on a level with the zero of the scale. The bottom of the cistern is raised or lowered by the screw, until the point of the needle and its image in the mercury precisely coincide. The observation is then made.

Several other forms of barometer will be described hereafter.

In order to construct good barometers, such that two or more may always stand (if possible) at the same height when in the same place, or may be correct indexes of the differences of height in different places, the following points must be attended to:—

1. The mercury must be chemically pure, and the interior of the tube must be freed from that coating of air which adheres to all bodies in their natural state, which, if allowed to enter with the mercury, would in time expand and render the vacuum above the mercury imperfect. It was formerly thought sufficient to expel the air by simply boiling the mercury in the tube previously to inverting it, and allowing the vacuum to form. De Luc found that all his barometers gave different heights until he boiled the mercury, after which the greater part of the difference disappeared; but he was not aware that, however carefully a barometer is prepared on this plan, it is liable to slow but certain deterioration by the infiltration of the air, as will be explained at greater length presently. The old plan was to boil a portion of the mercury first in the tube, and then to add the rest in a hot state, after which the boiling was repeated. One of the best tests of a good vacuum is when, by gently inclining the tube backwards and forwards, the mercury strikes the glass at the closed end of the tube with a hard, well-defined, and instantaneous tap. The vacuum can never be quite perfect; for, generally speaking, a small quantity of air will remain; and besides this, mercury itself will rise in vapour into the presumed vacuum [MERCURY], though not to so great a degree as to cause any perceptible pressure [ATMOSPHERE], and not more than it would rise in the air. The presence of mercurial vapour is a fact established as well by chemical tests as by the effect upon human health of breathing an atmosphere to which much of the metal has been exposed. If there be moisture in the supposed vacuum, the mercury will sink on applying the hand or any other warm substance.

Many barometers likewise, when the mercury is shaken in the dark, exhibit a luminous appearance in the vacuum over the mercury, and known as the *barometrical light*; the light being sometimes apparently uniform throughout the vacuum, sometimes appearing almost entirely on the surface of the mercury. This appearance was first noticed by Picard, and afterwards by Cassini, Lahire, &c. Though it appears to be an electrical phenomenon, we are not aware that any satisfactory explanation has been given of it, and particularly of the reason why it appears in some barometers and not in others, and why the same barometer sometimes loses the property, and afterwards recovers it. For a full account of the discovery, and of early hypotheses respecting it, see the first volume of De Luc's 'Recherches sur les Modifications de l'Atmosphère.'

In order to compare two barometers which are in different places, the temperature of the mercury must be attended to; for, as mercury expands with increase of temperature, a higher column of the fluid will be required to counterpoise a given weight of air. To observe the temperature of the mercury, a thermometer is attached to the best instruments, the bulb of which is in the cistern. All observed heights should be reduced to what they would be at some given temperature,- say the freezing point of water. And it must be remembered, that the scale itself on which the heights are measured, expands or contracts with the mercury. If the two expanded or contracted equally, there would be no occasion for any correction; but if the mercury expand more than the scale, it is the difference of the expansions by which the observed height will be wrong. Mercury expands more than the material of any scale which is ever employed.

In this country the scale is usually engraved on some mixed metal, and no very satisfactory value of the expansion can be given. It will be sufficiently accurate to suppose the expansion of mercury for every degree of Fahrenheit to be ·0001 of its bulk at the freezing point, and to neglect that of the scale altogether, which gives the following rule :—

To reduce an observed altitude to that of mercury at the freezing point, subtract the ten-thousandth part of the observed altitude for every degree by which the mercury is above the freezing point (of water, of course). At a height of 30 inches, and a temperature of 50° (Fahr.), this correction would be ·054 of an inch.

The expansion of the barometer-tube itself need not be attended to. The consequence of it is, that more mercury is drawn out of the cistern to form the requisite column; but the height of the column is unaltered.

(Remember that the *cubical* expansion, not the *linear*, must be used for the mercury in the formula.)

2. The height observed requires another correction for the *capillary* repulsion, by which it stands somewhat lower than it otherwise would do. On this subject a paper has recently been read to the Royal Society of London by Mr. Ivory, to which we refer for an accurate and clear account of the effects of capillarity on the barometric column, the effect of which is always to depress the mercury by a certain quantity inversely proportional to the base of the tube. The following table shows very clearly the amount of correction to be *added* :—

Diameter of Tube.	Correction for Unboiled Tubes.	Correction for Boiled Tubes.
Inch.	Inch.	Inch.
0·60	0·004	0·002
0·50	0·007	0·003
0·45	0·010	0·005
0·40	0·014	0·007
0·35	0·020	0·010
0·30	0·028	0·014
0·25	0·040	0·020
0·20	0·060	0·029
0·15	0·088	0·044
0·10	0·142	0·070

We must observe, that in the siphon barometer, No. 2, and also in the modification of it proposed by Gay Lussac, No. 14, no correction for capillarity is necessary; for the depressive force is equal on both sides. In all other barometers the capillary action of the cistern is insensible, owing to the magnitude of its diameter, so that only that of the tube need be attended to. Perhaps the best way of settling the exact amount of capillary depression would be by a very large number of observations upon two good barometers of different-sized tubes standing in the same place. The tube must be very exactly cylindrical, or the capillary correction will not be the same in all its parts.

3. The *index* correction must next be applied. This is the amount of difference between the particular instrument and the readings of the Royal Society's flint-glass barometer, or that of the Kew Observatory, when properly corrected. This correction however is generally attended to chiefly in the case of ships' barometers.

4. The barometer must hang quite vertically; for any deviation from the vertical converts the instrument, *pro tanto*, into the diagonal barometer, No. 7, and makes the divisions on the scale too small.

5. The scale is usually divided into tenths of inches, and is also furnished with a vernier, by which the height may be measured within the 200dth of an inch. [VERNIER]. Many observers profess to go nearer; but, considering the uncertainty (if we speak of thousandths of inches) of the corrections both of temperature, capillarity, of the zero point of the scale, &c., this must be considered as mere play. Whatever reliance may be placed on the mean of a large number of observations, we think we may safely defy any one to show an even chance that a single observation will be free from instrumental errors, even as far as the 200dth of an inch.

6. The exact determination of the level of the mercury in the cistern is in many barometers impossible. All the best instruments have some method of adjustment, either as described in Fortin's barometer, No. 15, or by placing a float on the surface of the mercury with a needle rising vertically from it, some point of which needle is adjusted by raising or lowering the bottom of the cistern.

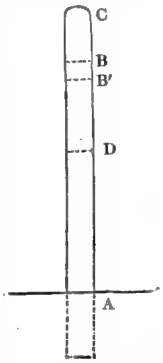
If a barometer be made, which is not a siphon barometer with uniform tube, No. 2, or with means of adjusting the lower level of the mercury, it should certainly be the simplest form of Torricelli's instrument, namely, a perfect cylindrical tube immersed in a perfectly cylindrical cistern. The larger the cistern, the less the error arising from variation of the lower level; the actual error may easily be calculated thus: Let K and k be the areas of the sections of the cistern and tube respectively; let a be the height of the column of mercury above the zero point at any time when that in the cistern is *at* the zero point, b the corresponding height at any other time, so that $b-a$ is the difference in *apparent* height; and let c be the depression of the mercury in the cistern below the zero point at this *latter* time; so that c is the error required to be *added* to the *apparent* height to give the *true* height. Now, by the laws of equilibrium of fluids, we shall easily have,

$$\mathrm{k} \times (b - a) = \mathrm{K} \times c.$$

$$\therefore c = \frac{\mathrm{k}}{\mathrm{K}}(b - a)$$

$$\therefore \text{ The } \textit{true} \text{ height required } = b + \frac{\mathrm{k}}{\mathrm{K}}(b-a) = b\left(1 + \frac{\mathrm{k}}{\mathrm{K}}\right) - \frac{\mathrm{k}}{\mathrm{K}}a$$

An *imperfect* barometer is one into which some air or gas has penetrated, and so caused a depression of the upper surface of the mercury below its proper level. When the barometer is to be employed in determining the relative heights of ground, it may not be possible to get this air out of the tube by any means in the power of the observer, and it then becomes necessary to have a formula by which a correction may be applied to the observed height of the mercury at any station in order to have the height at which the top of the column would stand if the tube were free from air.



For this purpose, before setting out, the height of the column of mercury in the defective instrument must be compared with the height in one which is perfect, in order to obtain the measure of the elasticity of the air which is confined in the upper extremity of the tube. Let A C be the length of the bore of the tube above A, the surface of the mercury in the cistern, A B the height of the column in a barometer free from air, and A B′ the observed height in the defective instrument. It being understood that these heights are read at the same time and place, so that the temperature and density of the air may be the same; and also that both instruments are provided with adjusting screws, so that the surfaces of the mercury in the two cisterns may be made to coincide with the zeros of the scales of inches. Then the pressure of the external atmosphere supporting the column A B, and the difference between that pressure and the pressure equivalent to the elasticity of the air in C B′ supporting the column A B′; it follows that the weight of a column of mercury in B B′ measures the pressure last mentioned; let this be represented by ml, in which l is equal to the height B B′.

Now, on removing the instrument to another, suppose a higher, station, let the observed height of the mercury in the imperfect barometer (no more air being supposed to have entered) be A D; then the air which, before, occupied the space C B′, occupies C D, and its elastic force is diminished in the inverse ratio of those spaces or heights therefore, if C B′ be represented by a, and C D by b,

$$b : a :: ml : m\frac{al}{b};$$

and the last term expresses the pressure of the confined air on D, the top of the column of mercury. This term added to the weight of the column of mercury A D, which may be represented by mh (h being the observed height A D), will be equal to the weight of the column of mercury at the same time and place in a barometer which is free from air. This last being represented by mh'; it follows that $h' = h + \frac{al}{b}$, or $\frac{al}{b}$ is to be added to the observed height, in order to obtain the corrected height of the column of mercury at the station.

Barometrical Measurement.—The use of the barometer for *Hypsometry*, or the measurement of heights, depends upon the fact of the diminution of atmospheric pressure as we ascend from the earth's surface. The best form of mountain-barometer is described in the article on 'Barometrical Measurements,' in the 'Encyclopædia Britannica.' The humidity of the air also materially affects its elasticity, so that the hygrometer, as well as the thermometer, should be used in correcting these observations; besides which, we must take into account the decrease of the earth's attraction at the point. The general method is as follows: Let x and x' be the heights in feet of the two stations, and let us suppose the atmosphere to consist of strata of one foot thick, throughout each of which the pressure is the same, but that in passing from one to another of them the pressure diminishes in a geometric progression whose ratio is r. This, we may add, is easily proved to be the case; see Goodwin's 'Course of Mathematics,' p. 332, from which we deduce the expression $r = 1 - \frac{g}{k}$, when g = force of gravity. Let the heights of the barometer at the two stations be h h', which are proportional to the atmospheric pressures, so that

$$\frac{h}{h'} = \frac{r^{x}}{r^{x'}} = \left(1 - \frac{g}{k}\right)^{(x - x')}$$

$$\therefore \quad x - x' = \frac{\log \frac{h}{h'}}{\log \left(1 - \frac{g}{k}\right)}.$$

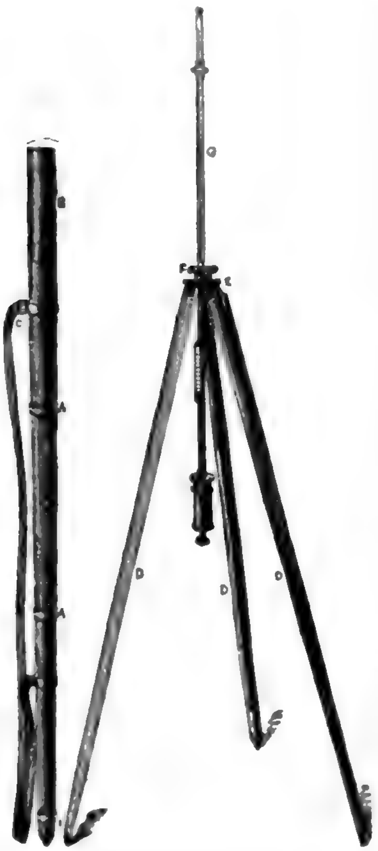
The rules for finding the heights by the barometer are summed up in the following words :—

1. Correct the length of the mercurial column at the upper station, adding to it the product of its multiplication into twice the difference between the degrees on the attached thermometers, the decimal point being shifted four places to the left.

2. Subtract the logarithm of this corrected length from that of the lower column, multiply by 6, and move the decimal point four places to the right; the result is the approximate elevation expressed in English feet.

3. Correct the approximate elevation by shifting the decimal point three places back to the right, and multiplying by twice the sum of the degrees on the detached thermometers; this product being now *added* will give the true elevation.

The annexed figures represent a convenient form of portable barometer manufactured by Messrs. Negretti and Zambra. The first figure represents the instrument packed in its case with a strap C, and the other figure mounted for an observation; D D is the tripod stand, and G the barometer tube.



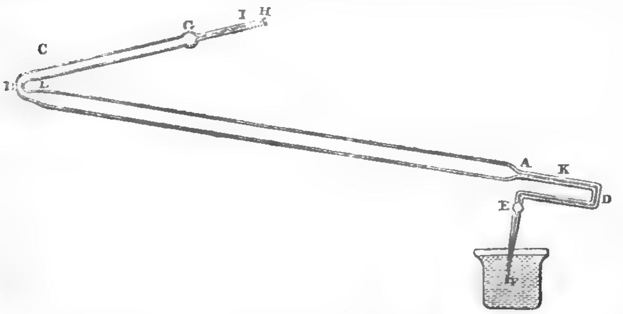
Standard Barometer.—In preparing a standard barometer for the Royal Society, the late Professor Daniell, of King's College, endeavoured to get rid of the objections to the boiling of the mercury in the tube by first abstracting the air by means of an air-pump, the presence of moisture being avoided by the use of sulphuric acid. Accordingly a barometer tube was fitted with a stopcock, which was screwed into the under surface of the pump-plate; while, on the upper surface, was a glass dish perforated in the centre, and containing the acid. In this dish was placed a stand with glass legs for receiving a funnel, the stem of which, being drawn out into a capillary tube, passed down into the mouth of a small paper cone resting upon the tube. The aperture at the upper part of the stem was closed by an iron plug, between which and the capillary opening cotton was placed. The glass funnel was filled with carefully prepared mercury, and the whole was covered with a glass receiver, furnished at the top with a sliding rod, the lower end of which could be screwed into the plug so as to draw it up and replace it. The air was now exhausted to ·5 inch, and the plug being withdrawn, the mercury was allowed to trickle into the tube. In its fall it was, however, broken into globules, which formed minute cavities as the tube was filled. As these cavities could not entirely be got rid of, the apparatus was varied by passing a small tube to the bottom of the barometer tube, so that the mercury could trickle down this and deliver itself slowly into the barometer tube; by this means the mercury rose in the latter in perfect and uninterrupted contact with the glass. The success of this experiment was such, that under ordinary circumstances it would not have been thought necessary to boil the mercury in the tube, but the prejudices of the day required that this troublesome and hazardous process should be gone through. Many tubes were destroyed in the boiling, after all the trouble of measuring and filling had been taken. The tube finally selected was 33¾ inches long, and ·530 inch bore. The boiling was not performed, however, in the ordinary manner, over a charcoal fire, but during the process of filling under diminished pressure, as already described. When 17 inches of mercury had been introduced, the tube was gradually heated before a fire, and a large spirit lamp flame was applied to the upper part of the mercury; when this had reached the point of ebullition the boiling was slowly continued downwards, and when it had reached the bottom it was again as gradually conducted to the top. "The bubbles of vapour freely passed, with the assistance of a slight degree of agitation, from one end of the column to the other; and very bright flashes of green light accompanied their extrication. One minute globule of air alone was detected during the heating, notwithstanding the diminished pressure, and this was readily extricated; and there was not the slightest condensation of moisture visible in the cold portion of the tube." The cooling was conducted very slowly; when the second portion of mercury was introduced, making the column equal to 29¼ inches, the air was abstracted, and the boiling begun as before from the top and carried downwards to about two inches below the union of the two portions of mercury. The last 3½ inches of the tube were filled up with hot mercury, and the whole was left for 48 hours. When the tube was inverted in the cistern, this great body of mercury did not descend until it had received two or three smart concussions; a good proof of the displacement of air. By vibrating the mercury in the tube, beautiful green flashes of barometric light were seen in the vacuum, and the crackling sound of electrical excitation was heard on approaching the finger.

This fine instrument was not destined to remain long a faithful representative of the atmospheric pressure. The mercurial column, which was originally perfectly bright and compact, became, in the course of some months, dull and speckled, arising from the pressure of minute air-bubbles; the air, in fact, had insinuated itself between the metal and the tube where the latter dipped into the cistern, and creeping up into the Torricellian vacuum, opposed a resisting medium to the oscillations of the column; which, consequently, no longer represented the atmospheric pressure, but the difference between that pressure and that of the air contained in the space at the top of the tube. Hence it was evident that all barometers, constructed with a straight tube dipping into an open cistern of mercury, must be liable to a constant process of deterioration; and consequently all the registers which had been so industriously kept by scientific men in various parts of the world, were no longer trustworthy. The effect of this deterioration would be to produce a gradual lowering of the mean annual height of the barometer; but in order to trace it, it was necessary to compare periods of five or six years or more with each other. The 'Ephemerides' of the Meteorological Society of the Palatinate furnished the materials for this comparison. Taking the series of observations made at Mannheim for the twelve years 1781 to 1792 inclusive, and dividing them into two periods of six years each, the mean of the last period was found to be ·62 inch lower than that of the first period. A similar comparison for the observations made at Padua gave ·044 inch lower for the second period than for the first. For Rome, the difference was ·114 inch; for Buda, ·035 inch; for Brussels, ·044 inch; for Munich, ·026 inch; for Peisenberg, in Bavaria, ·026 inch; and for Mount St. Gothard, ·026 inch. These examples establish the fact of the gradual depression of the mercurial column by the infiltration of air; and it may further be seen, that the amount of the effect depends in some degree upon the elasticity of the atmosphere in which it takes place. The five series of observations, the mean pressure of which is 29·235 inches, show an average depression of ·059 inch in 12 years; while the three series, the mean pressure of which is 25·977 inches, show a depression of only ·026 in the same period.

The remedy proposed by Professor Daniell against this serious source of deterioration, which would render barometrical observations comparatively worthless, was to weld to the barometer tube near its open end a ring of platinum, so that when the tube was dipped into the cistern, the mercury, by wetting the platinum, would produce such perfect adhesion as effectually to exclude the infiltration of atmospheric air. Accordingly this plan was adopted, and for many years all the best barometers were furnished with a platinum guard. It was thus supposed that the evil complained of, was most effectually cured; but time, which is as delicate a test as any that a chemist can offer, showed that the platinum guard was not free from defects. The mercury formed an amalgam with the platinum, which, during the oscillations of the barometer, got sucked up into the vacuum, and, clinging about the tube, impeded observation. The next remedy was the simple and apparently obvious one of turning up the end of the tube, as represented in the annexed figure; but as this involved a new method of filling, we must, in order to describe it, again recur to the difficulties of boiling, especially when the tube is of large dimensions.

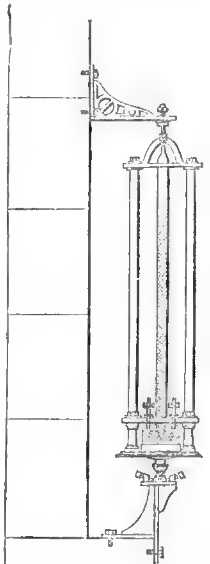
In the years 1853 and 1854 several attempts were made, under the superintendence of the Kew Observatory Committee of the British Association, to prepare a barometer tube of large size in the usual manner. Mr. Negretti succeeded in filling tubes fully one inch in internal diameter; but many of these, before they could be mounted, broke spontaneously, some within a few hours, and others after an interval of several days after the boiling. Two or three tubes were mounted, but did not work satisfactorily; the adhesion of the mercury to the glass was such, that when the barometer was set up the convexity of the top of the column was destroyed, and the surface even became concave; after a few days' working, rings of dirt or other impurity were formed on the glass near the top of the column, and they continued to increase so as to interfere with observation. Nevertheless, care had previously been taken to render the mercury chemically pure; and, when examined by Professor Miller of King's College, no impurity was detected in it. The great heat to which the glass is exposed during the boiling, applied as it is in an irregular and unequal manner, probably has the effect of reducing the glass to its unannealed condition, in which the particles are held in a state of unstable equilibrium (as in the Bologna phial), so as to be liable to be overturned from a very slight cause. The fouling of the mercury seems to have arisen from impurities in the glass tubes; for when greater care was taken by the glass-blower, the effect on the mercury was decidedly diminished; and when the tubes, before being filled, were thoroughly cleansed by sponging them with whiting and spirits of wine, a satisfactory result was obtained; for after a year's trial it was found that the top of the column presented a good convexity in all states of the barometer, with only a very slight trace of dirt. In this case the standard barometer was filled, not by boiling, but by a method devised by Mr. Welsh of the Kew Observatory, and described by him in a paper communicated to the Royal Society in 1856.

The tube to be filled was first prepared in the following manner: To its upper end was attached a bent capillary tube, A, D, E, F, with its bore much contracted at the apex, D, with a small bulb at E, and drawn out to a fine point at F, where it was sealed. To the lower end of the large tube was attached a smaller tube B, C, G, ·3 inch bore and 10 inches in length, and to this was added the short capillary tube, G H, with a bulb at G. The end H of the capillary tube was next connected with a good air-pump, and the air was very slowly extracted



while the whole tube was being strongly heated by passing a large spirit-flame along it. When the air had been as far as possible extracted in this way, and while the air-pump was still being worked, and the heat still applied, the capillary tube G H was sealed at I by means of a blowpipe flame. When the tube had cooled it was placed at a small inclination with the end F in a vessel of well-boiled mercury, when, the point F being broken off under the mercury, the metal rose in the tube by atmospheric pressure, and continued to rise until the bulb at G was more than half-filled, the remaining space being occupied by the air which the pump had not extracted. The pressure of this residual air was calculated to be less than ·05 inch. The basin of mercury was then withdrawn from beneath the tube, leaving the point F exposed, while the small tube remained quite filled with mercury. The blowpipe was then applied at F, and the opening sealed. When the glass at F had cooled, the tube was placed erect, the mercury separating at the contracted part, D, leaving the tube from D to F filled or very nearly so, and from D to A empty. The tube was next sealed at K, and the portion K D E F removed. Lastly, the lower end of the tube was broken under mercury at C, leaving about an inch of the siphon. This barometer tube has an internal diameter of 1·1 inch. It is supported over a glass cistern, in a strong brass frame, secured by brackets to the wall of the old mural quadrant of the Kew Observatory, the height of the mercury being measured by a cathetometer fixed to the same wall at a distance of five feet. A conical point at the lower end of a short rod of steel is adjusted by a screw to the surface of the mercury in the cistern, as shown in the figure. At the upper end of the steel rod, and above the level of the glass cistern, is a fine mark, the distance of which from the conical point is 3·515 inches. In making an observation, the lower point is adjusted to exact contact with the mercury in the cistern; the telescope of the cathetometer is then levelled, and its horizontal wire made to bisect the mark on the upper end of the steel rod; the scale reading of the cathetometer being noted, the telescope is then raised, again levelled, and the wire made a tangent to the surface of the mercury in the tube, the cathetometer scale being again observed; the difference between the two readings of the cathetometer, added to the length of the steel rod, is the column of mercury. To prevent light from being reflected into the telescope from the surface of the mercury in the tube, a moveable screen, the upper part of which is black and the lower part of oil-paper, is so adjusted as to shut off all light that comes from a higher level than the top of the mercury, by which means the surface of the column presents in the telescope a well-defined dark outline. A window behind the barometer illuminates the paper screen by day, and a lamp by night. A thermometer with its bulb in the mercury of the cistern, gives its temperature, and the brass scale of the cathetometer is corrected by means of the usual tables.

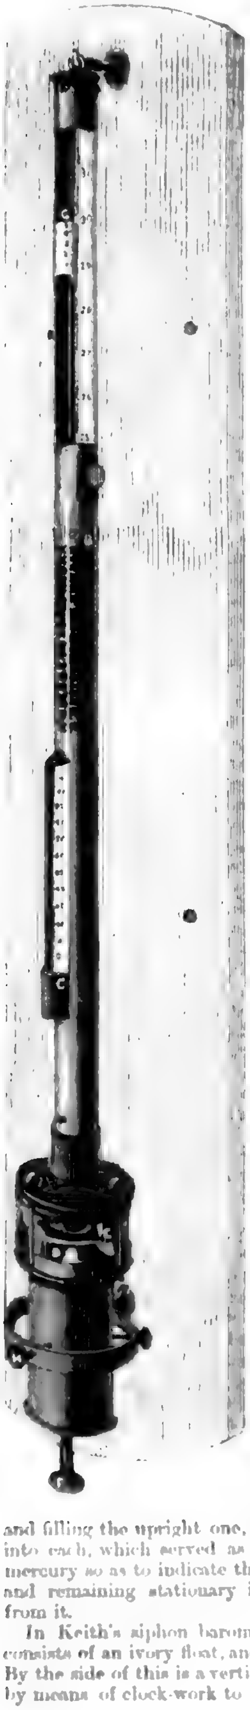
This fine instrument is used as the standard for correcting the barometers supplied by the Board of Trade to captains of merchant ships, willing to make observations at sea, and also to various meteorological stations in the colonies.* The method of testing is described by Mr. Welsh, 'Phil. Trans. 1856'; and also in the 'first number of 'Meteorological Papers, published by the authority of the Board of Trade, 1857,' from which we gather the following particulars: In the barometers used at sea, the usual method of adjusting the mercury in the cistern to the zero point or the reverse, previous to an observation, cannot be adopted on account of the motion of the ship, which motion would produce in an ordinary barometer an oscillation of the mercurial column known by the name of *pumping*. To prevent this, part of the tube of the marine barometer must be very much contracted, one consequence of this construction being that the index correction varies through the range of scale readings in proportion to the difference of capacity between the cistern and the tube. To find the index correction for a land barometer, comparison with a standard at any part of the scale at which the mercury may happen to be, is usually considered sufficient; but to test the marine barometer it is necessary to find the correction for scale readings at about each half-inch throughout the range of atmospheric pressure to which it may be exposed. Hence it is necessary to have means at command for changing the pressure of the atmosphere on the surface of the mercury in the cistern. For this purpose the barometers to be tested are placed with a standard in an air-tight chamber of iron from which a portion of the air can be pumped out, so as to diminish the pressure, or air can be forced in so as to increase the pressure. The tube of the standard is contracted as in the marine barometer, but provision is made for adjusting the mercury in its cistern to the zero point. The upper part of the air-chamber contains glass windows through which the scales of the thermometers are visible, but as the verniers cannot be got at, the height of the mercury is read by means of the fixed vertical scale and cathetometer already referred to. The fixed scale is 5 or 6 feet from the chamber, and its divisions exactly correspond with those on the tube of the standard: a vernier and telescope slide on the scale by means of a rack and pinion; the telescope has two horizontal wires, one fixed and the other moveable by a micrometer screw, so that the difference between the height of the column of mercury, and the nearest division on the scale of the standard, and also of all the other barometers placed by the side of it for comparison, can be measured either with the vertical scales and vernier or the micrometer wire. In this way the barometers are usually tested at every half-inch, from 27·5 to 31 inches. In some barometers the errors are so large as to read half-an-inch and upwards too high, while others read as much too low. In some cases those which were correct in some part of the scale, were found to be from half-an-inch to an inch wrong in other parts. Indeed the marine barometer, until lately in common use, was so faulty in construction that the cistern was not large enough to contain all the mercury, which descended in a low atmospheric pressure, so that in some cases it was found that 29 inches was the minimum pressure that the barometer could indicate.



The marine barometer recently introduced on the recommendation of the Kew Committee, is a superior instrument. The diameter of the cistern is about $1\frac{1}{4}$ inch, and that of the tube about $\frac{1}{4}$ inch. The scale, instead of being divided into inches in the usual way, is shortened in the proportion of about 0·04 of an inch for every inch, which prevents the necessity for applying a correction for difference of capacity between the cistern and the tube. To check the pumping of the mercury the tubes are so contracted through a few inches, that when first suspended the mercury may be twenty minutes in falling from the top of the tube to its proper level. This contraction of the tube causes the marine

* In the year 1853, a conference of maritime nations was held at Brussels on the subject of meteorology at sea. The report of this conference was laid before Parliament, which voted a sum of money for the purchase of instruments, and the discussion of observations under the superintendence of the Board of Trade. Arrangements were then made in accordance with the views of the Royal Society and the British Association for the Advancement of Science, for the supply of instruments properly tested.

barometer when used on shore to be always a little behind an ordinary barometer, varying in amount according to the rate at which the mercury is rising or falling, and ranging from 0·00 to 0·02 of an inch. It is supposed that as the motion of the ship at sea causes the mercury to pass more rapidly through the contracted tube, the readings are about the same as they would be if the tube were not contracted.



The standard barometer manufactured by Messrs. Negretti and Zambra on Fortin's principle (No. 15), in which the reading is made from an ivory point in the cistern, is represented in the adjoining figure. The tube, which is filled by boiling, is enclosed within a brass tube, B, furnished at the upper part with two longitudinal openings opposite each other; on one side of the front opening is the scale of English inches divided to show, by means of a vernier, $\frac{1}{500}$th of an inch; on the opposite side is sometimes divided a scale of French millimêtres, reading also by a vernier to $\frac{1}{10}$th of a millimêtre; the reservoir, or cistern of the barometer is of glass, closed at bottom by means of a leather bag, acted upon by a thumb-screw, F, passing through the bottom of an arrangement of brass-work, by which it is protected. This instrument is sent out in three parts, packed separately for safety in carriage. They consist first, of the barometer-tube and cistern, filled with mercury; secondly, the brass tube, with its divided scale and thermometer, C; and thirdly, a mahogany board with a bracket at the top, and a brass ring with three adjusting screws at the bottom. The board is to be fixed as nearly vertical as possible; the barometer tube and its cistern are screwed into the brass tube; and an experiment is made to see whether the tube is free from air. For this purpose the screw at the bottom of the cistern is lowered three or four turns, so that the mercury in the tube when held upright may fall 2 or 3 inches from the top. The mercury is then made to strike the top of the tube as already noticed; if a sharp tap be heard, the instrument is perfect; but if the tap be dull, or not audible, there is air above the mercury, which must be driven into the cistern by inverting the instrument and gently tapping it by the hand. The barometer is next suspended on the brass bracket, and the cistern passed through the ring at the bottom, and when it has settled in a vertical position it is clamped by means of the three thumb-screws, H. Before making an observation, the mercury in the cistern must be raised or lowered, by means of the thumb-screw, F, until the ivory point, E, and its reflected image, are just in contact; the vernier is then moved by means of the milled head, until its lower termination just excludes the light from the top of the mercurial column, when the reading is taken by means of the scale on the limbs and vernier.

Self-registering Barometers.—Various attempts have been made so to construct barometers that they shall register their own proceedings. In 1830, Dr. Traill constructed an apparatus consisting of two diagonal barometers, one inverted and resembling in principle the rectangular barometer; both were attached to the same frame, but before bending and filling the upright one, a piece of smooth steel wire was introduced into each, which served as indices by being driven forwards by the mercury so as to indicate the maximum or minimum for a given time, and remaining stationary in the tube when the mercury retreated from it.

In Keith's siphon barometer, as improved by Bryson, the register consists of an ivory float, and a kneed wire ending in a small knife-edge. By the side of this is a vertical cylinder of tinned iron, japanned, made by means of clock-work to move round on its axis once in 24 hours; the surface of this cylinder being thinly coated with a mixture of chalk and water, the knife-edge is made to touch the cylinder every hour, and by cutting through the chalk shows a black line on a white ground. At the end of 24 hours the first cylinder is removed, and a second one substituted, while the marks on the first can be read off and recorded by means of a scale of equal parts.

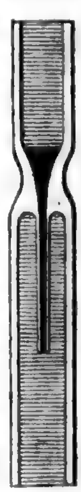
Messrs. Negretti and Zambra register the highest and lowest readings in the following manner:—To the longer leg of a siphon barometer, 8 inches from the top, is joined a bent glass tube, carried up for 6 inches parallel to the principal tube, and joining it at 2 inches from the top. The mercury flows freely in and out of this tube, and maintains the same level as that in the larger tube. This bent tube contains a small piece of steel, which is kept in position by means of fine glass springs: as the mercury rises the steel is pushed up, and remains stationary when the mercury recedes. The lowest readings are indicated by a similar contrivance in the shorter leg.

Mr. Yeates' registering apparatus consists of a revolving cylinder 4 inches in length, around which is paper ruled into thirty-one vertical portions, and horizontally into 10ths of inches, and numbered from 27 to 31 inches. To the receiver is attached a pencil for marking the paper. The ivory point is adjusted to the surface of the mercury by means of a plunger.

Of late years, the self-registration of the barometer has been effected in meteorological observatories by means of photographic apparatus. The principle of the contrivance is to direct the light of a lamp through the Torricellian vacuum upon a surface of sensitive paper, as it is gradually unwound from a cylinder. In this way a broad trace is left on the paper, the breadth of which varies with the height of the mercury in the tube.

Attempts at self-registration have also been made by furnishing the upper part of the tube with wires, connected with certain voltaic arrangements, in which the currents are closed by the ascent of the mercury in the tube. M. Hardy, an instrument maker of Paris, has fitted a siphon barometer with an apparatus consisting of a float in the open limb, which float acts upon an aluminium rule; this is furnished with a pencil, and is made to move up and down before a vertical cylinder, but the pencil is at the distance of one millimêtre from the cylinder. The cylinder is moved by clockwork, which every five minutes sends an electric current through an apparatus which sets a hammer in motion, and this striking on the barometer tube performs the office of the finger of the observer in tapping the instrument so as to produce a more exact level of the mercury. Half a minute after the hammer has ceased, the clock sends a current through an electro-magnet, the armature of which strikes on the aluminium rule, and forces the pencil up to the register paper on the cylinder.

Miscellaneous.—Various forms of barometer were brought under the notice of the Jury (Class X) of the Great Exhibition of 1851. Mr. John Griffith exhibited a barometer so constructed as to give the power at all times of securing a vacuum above the mercury. The top of the tube is furnished with a crook for the purpose of trapping all the air which may be above the column; the tube is bent at the lower part, while near the middle of the tube is a joint with a trap; there is also a stop-cock, and a stretcher for closing the open part of the glass tube when necessary. The reading is by means of a brass bar, carrying two cylinders at the distance of 29·722 inches, and moved up and down by means of a steel screw, with twenty-five threads to the inch, working in a matrix by means of a milled head. The bar has a pointer for reading to 100ths of an inch, and there is also suitable apparatus for reading to 1000th of an inch.



Messrs. Negretti and Zambra had a barometer with an air-trap glass cistern, to be read off by means of a sliding scale adjustable to the surface of the mercury by means of a fine ivory point. The tube and cistern were blown together, and at intermediate junctures were three points and three small tubes or traps, communicating with each other to prevent the admission of air. The construction of these air-traps will be understood by referring to the accompanying figure, in which it will be seen that air, creeping up the tube, would evidently pass up into the hemispherical part or trap, where it would be retained instead of passing up that part of the tube which is drawn nearly to a point, and leads directly into the Torricellian vacuum.

The same excellent makers also exhibited a folding barometer, consisting of a tube with a steel stop-cock in the centre, which when folded up, carries with it the two valves of the tube with which it is connected.

In Mr. Abraham's barometer the scale was suspended over a pulley by means of a counterpoise, the lower end of the scale being connected to a float in the shorter leg of the siphon. Mr. Ross had a self-compensating barometer on the same principle.

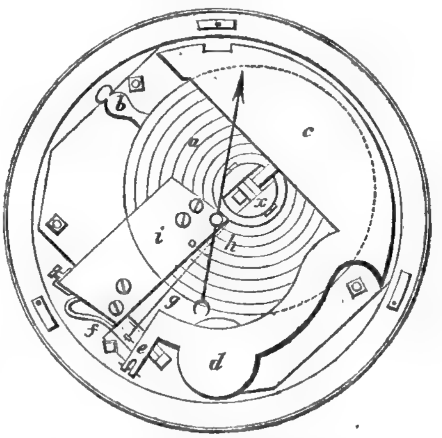
Among the numerous forms of barometer which are being constantly devised, we may mention that by M. Trouessart, in which the curved portion of a siphon barometer is made of caoutchouc, which allows the observer to augment the capacity of the barometer chamber at will, and consequently to vary the height of the mercurial column so as to be able to deduce from it the atmospheric pressure. In M. Blondeau's instrument, the dimensions of which are very much less than in the ordinary form, a volume of air of the pressure intended to be measured is taken and dilated so as to occupy double its former volume. Under such circumstances, the elasticity of the air producing equilibrium at the pressure of only half an atmosphere, causes such a difference in the height of the mercury in the tube communicating with it, as to show at once the value of the pressure of this half-atmosphere, whence may be deduced the pressure of the air at the time of observation.

Water-Barometer.—Attempts have been made at various times to construct a *water-barometer*, under the idea that its greater oscillations as compared with the mercurial-barometer might throw some light on several points of physical science. Mariotte formed a water-barometer, and noticed that when the mercurial-barometer stood at 28 *pouces*, the water indicated 31½ *pieds*. "Ce qui donne," he remarks, "le rapport du mercure à l'eau de 13½ à 1." Otto Guericke had a water-barometer rising along the wall with a toy of the shape of a man floating on the top of the water; the lower part of the tube was concealed under the wainscoting, so much so, that the little image only made its appearance in fine weather. This contrivance was named an *Anemoscope* or *Semper Virum*. It does not appear that in these instruments any attempts were made to purge the water of air by boiling, and to prevent its re-absorption, nor did the tube consist of one whole length. These objections Professor Daniell determined to obviate in the water-barometer, which it was proposed to erect in the hall of the Royal Society at Somerset House, in the year 1831. The tube was drawn without any difficulty by Messrs. Pellatt and Co., it was 40 feet in length, 1 inch in diameter at its lower extremity, and 0·8 inch at its upper. The tube was conveyed in a packing-case to its position in the Society's Hall, and its lower end was passed through a stuffing-box into a steam boiler, so arranged that the water could be first thoroughly boiled, and then, by closing a stop-cock, raised in the tube by the elastic force of the vapour acting upon its surface until it issued in a jet from a small stop-cock at the top of the tube. This operation was at length, after some failures, conducted successfully. As the apparatus cooled the column of water subsided until it was balanced by the pressure of the atmosphere, and the water in the boiler, which now constituted the cistern of the barometer, was covered with half-an-inch of castor oil to prevent the atmosphere from communicating with the water, and the air from being absorbed. The adjustment of the scale with the necessary correction was next attended to. Of course one of the most important corrections would be for the elasticity of the aqueous vapour at the observed temperature. An extensive series of observations during two years showed that the instrument was undergoing deterioration, and on opening the cistern it was found that some of the liquid had escaped, and that the oil had undergone decomposition. On taking some of the water out of the boiler and placing it under the receiver of an air-pump, air-bubbles were extricated in abundance, showing that the attempts to prevent the absorption of the air had failed. The indications of this instrument, however, clearly established the fact that the water-barometer precedes by one hour the barometer of half-an-inch bore, and the latter, the mountain-barometer of 0·15 inch bore by the same interval in their indications in the horary oscillations. It was also curious to watch the water-barometer in windy weather; the column of water appeared to be in a perpetual motion resembling the slow action of respiration. At the end of 1844, the barometer was examined, the gas collected in the vacuum proved to be pure nitrogen, the oxygen having been absorbed in passing through the oil, making it rancid and producing other changes. In January, 1845, the instrument was emptied, cleaned, and refilled as before, when instead of covering the water in the cistern with oil, a solution of caoutchouc in naphtha was substituted to the depth of between two and three inches. This, however, did not prevent the entrance of air, so that the attempt to establish a water-barometer must be regarded as a failure.

In the theatre of the Natural Philosophy class in the University of Edinburgh, is a water-barometer constructed by Adie, not for meteorological purposes, but as a class illustration for exhibiting the Torricellian experiment in a striking manner. It consists of a fine drawn tube of tin of ½-inch bore, rising 30 feet from a copper basin, enclosed under the benches of a class below, and cemented at the top to a glass cylinder, 2 inches wide and about 6 feet high, exposed to view but terminating in a small basin containing water. Both ends of this compound column are fitted with stop-cocks, which may be opened or shut at pleasure by means of concealed wires.

It may also be noticed, that in the Great Exhibition of 1851, Mr. Brown exhibited a barometer 39 feet high, containing two immiscible liquids of nearly equal specific gravity, and their point of meeting which may be placed at any part of the scale, was indicated by one liquid being coloured.

The Aneroid Barometer.—The weight of a column of air, which in the ordinary barometer acts on the mercury, in the aneroid presses on a small round metal box, from which nearly all the air has been extracted, and as its indications are obtained without the use of mercury or any other fluid, we have the etymology of the word in the Greek, ἀ without, and νηρὸς fluid.* It was invented some years ago by M. Vidi of Paris. It is inferior in value to the mercurial barometer, but has some advantages in sensibility and portability. It admits of being carried in the pocket, and may be used on a journey in situations where the mountain barometer would be inconvenient. Its variations from temperature seldom exceed $\frac{1}{10}$th inch in a range from 28° to 80°, a variation to which the mercurial barometer is liable, only in this case its exact amount for every degree of temperature has been determined.† The external appearance of the aneroid is that of a brass box with an enamelled dial face covered with glass. In the centre of the dial is a pivot for the reception of a needle, which moves over a series of graduations marked from 28 to 31 to represent the inches of the ordinary barometer, and over these graduations are the usual words 'stormy,' 'much rain,' 'rain,' &c. Attached to the face are also two thermometers, one graduated according to Fahrenheit, and the other according to the centigrade scale. On removing the dial-face, but retaining the needle, we have the appearance represented in the accompanying figure, in which *a* is the flat circular box made of white metal, previously exhausted of air through the short tube *b*, and made air-tight by soldering: the upper and lower surfaces of the box are corrugated in concentric circles, which improves the elasticity of the metal. This box is attached to the bottom of the brass external case. In the centre of the upper surface of the elastic box is a solid cylindrical socket *x*, about half-an-inch high, to the top of which the principal lever *c*, *d*, *e*, is attached; this lever brings the box into a state of tension by separating the surfaces, and rests partly on a spiral spring *d*, and partly on two fulcra, having knife-edges, which are free to move. The end *e* of the principal lever is attached to a second lever *f*, from which a fine watch-chain *g*, extends to *h*, where it works on a drum attached to the arbour of the hand. A hair-spring at *h*, attached to the metallic plate *i*, regulates the motion of the hand. As the weight



of the atmosphere becomes increased or diminished the surface of the box becomes depressed or elevated, while the spiral spring *d*, upon which the principal lever rests, shares in the motion, which is thus communicated through the levers to the arbour of the hand at *h*. At the back of the instrument is a screw for the purpose of adjusting the hand to the height of the mercurial barometer.

The neglect of this last point has led to considerable misconception on the part of persons using the instrument, and also on the part of some writers who have described it. They regard the aneroid as an independent instrument, which it was never intended to be, for it requires to be set originally by a barometer, and to be adjusted from time to time by reference to the same instrument. In the Meteorological Papers published by the Board of Trade there is the following testimony to its value: "The aneroid is quick in showing the variation in atmospheric pressure, and to the navigator who knows the difficulty of using barometers at times, this instrument is a great boon, for it is steady under all circumstances of weather, at the same time giving indications of increased or diminished pressure. It is a good weather glass, to be suspended on or near the upper deck for easy reference. In ascending or descending elevated land, the hand of the aneroid may be seen to move like the hand of a watch, showing the height above the level of the sea." Mr. Belville of the Royal Observatory, Greenwich, in his "Manual of the Barometer," in giving the meteorological results of a tour in Wales obtained by means of the aneroid, says, "It was a delightful companion and highly useful; its indications preventing many an excursion which would have ended in disappointment."

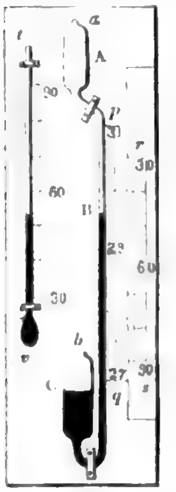
* It has been however said, that M. Vidi intended this word to be derived rather from ἀνὴρ, a man, because the pressure is similar to that produced by the same cause on a man's body. Thence he intended to call it an aneroid baroscope. [BAROSCOPE.] The derivation given above, is probably more correct. Others derive it from ἀνέρομαι, to inquire or observe.

† The inventor has introduced into the vacuum-box a small portion of gas, which, changing its bulk with change of temperature, is intended to act as a compensation for the effects of heat and cold.

A *Metallic Barometer*, a modification of the aneroid, was invented by Bourdon, in 1850. It consists of an elastic flattened tube of metal, completely exhausted of air, and bent very nearly into the form of a circle. In this condition the flattened tube has the property of expanding: the ends separating further from each other when the atmospheric pressure is diminished, while a contrary effect takes place when the pressure increases. A lever is attached to the end of the tube, and is connected by suitable mechanism to an index hand, which traverses a divided dial-plate. This plate is graduated by placing the instrument, together with a standard barometer, within the receiver of an air-pump, and the points of coincidence are determined by varying the pressure. An instrument of this kind is well adapted for steam-engines, gasometers, &c., since it will measure a pressure up to 500 lbs. and upwards on the square inch.

The *Sympiesometer* (from *συμπιεσις, compression*, and *μέτρον, measure*), was invented by Adie, of Edinburgh, in 1819, to serve as a barometer, for the purpose of measuring the pressure of the atmosphere, or of exhibiting the variations of its density near the earth. An account of its construction is contained in the first volume of the 'Edinburgh Journal of Science.' It consists of a glass tube B about 18 inches long and seven-hundredths of an inch in diameter internally: at the upper extremity is a cylindrical vessel A, half an inch in diameter internally and two or three inches long; and the lower extremity, being turned upwards, terminates also in a vessel C. The vessel A and the upper part of the tube B are filled with an elastic fluid, such as hydrogen gas, while the vessel C and the lower part of the tube contain almond-oil, coloured with some tincture such as that of anchusa root.

In order to introduce the gas and oil, the extremities *a* and *b* of the vessels A and C being open, and the former extremity being drawn in the form of a slender tube, the instrument is quite filled with mercury; when, being held in a horizontal position with the orifice *b* covered by the finger, that the mercury may not run out, the slender pipe at *a* is put in communication with the gasometer. The hydrogen gas entering at *a*, and the instrument being now brought to a vertical position, on removing the finger from *b* the mercury will flow out till its upper surface is at the same level in the tube B and the vessel C, the gas occupying its place in the former. The extremity *a* is then hermetically sealed, and, the instrument being inverted, the mercury in C runs out, while that which remains in the tube B prevents the gas from escaping. The instrument being afterwards returned to its former position, the vessel A uppermost, the oil is poured into the vessel C: then, the gas being heated, by its expansion it drives the mercury in B into the vessel C; and, the instrument being now held in an inclined position, the oil is by the pressure of the atmosphere forced into the tube B in proportion as the gas by cooling becomes contracted in volume. The remaining mercury is lastly poured out of the vessel C; and the end *b* being left open, the pressure of the atmosphere on the oil is, the instrument being again put in a vertical position, a counterbalance to the weight of the column of oil in B and to the expansive force of the compressed gas which is in the upper part of the tube and in the vessel A.



In order to form a scale for the sympiesometer, the instrument, together with a good barometer and a thermometer, must be placed in a glass receiver in which, by proper syringes, the air may be rarefied or condensed at pleasure: then, on bringing the air in the receiver successively to such states, with respect to density, that the top of the column of mercury in the barometer may stand at 27, 28, 29, and 30 inches, and marking the points on the tube or frame of the sympiesometer at which the top of the column of oil stood when the air was in those states, the distance between every two of these points being divided into one hundred equal parts, the scale *p q* of the instrument is constructed. The particular graduation at which, on the scale, the top of the column of oil stands at any time should indicate the number of inches and hundredths of an inch at which the top of the column of mercury in a barometer would stand at the same time in the same place.

But the volume of the hydrogen gas changes in consequence of variations in the temperature of the atmosphere; and therefore a correction, depending on the amount of the variation in the volume of gas for given increments of heat, should be applied to the number of the graduation on the scale of the sympiesometer in order to obtain the true height of the mercurial column in a barometer.

But, to avoid the trouble of computing and applying this correction, the scale *p q* of the sympiesometer is made to slide on one side of a scale *r s* which is graduated like that of a thermometer, by communicating different degrees of heat to the vessel A while the pressure of the atmosphere on the upper surface of the oil in C remains the same (suppose that which corresponds to 29½ inches on the scale of a barometer) and observing the points at which the top of the column in B stands: these points on the scale *r s* are numbered so as to express, in degrees, the temperature of the gas; and the scale *p q* being moved till its index (at 29½ inches) coincides with the degree of the scale *r s* corresponding to the temperature of the atmosphere, expressed by the degree of a thermometer *t v* attached to the instrument, the graduation on *p q* corresponding to the top of the column of oil in B expresses the height of a column of mercury in a barometer.

Dr. Robert Gordon, the writer of the article Meteorology in the 'Edinburgh Encyclopædia,' having made a series of observations for the purpose of comparing the indications of the sympiesometer with those of a barometer, found that the former stood higher than the latter by quantities varying between 0·03 inch and 0·017 inch, the temperature varying between 42°·3 and 62°·6 (Fahr.): he found at the same time that, in general, the difference between the indications of the two instruments increased as the temperature and pressure diminished. The excess of the indications given by one instrument over those given by the other may be conceived to have arisen from some inaccuracy in the construction of the sympiesometer: but the variation of the excess is not so easily accounted for; it may, however, be supposed to be caused in part by the expansions of the gas not being exactly proportional to the increments of heat, a circumstance which is assumed in the subdivisions of the scale *r s*, between each of the complete inches, being made equal to one another, and in part from some absorption between the oil and the gas. It is inferred, therefore, that the indications of the sympiesometer cannot always be relied on as accurate measures of the density of the atmosphere; but, since it has been observed that the instrument is frequently affected by changes in that density, which are too small to be perceived on the scale of a barometer; and since it is well known to be less deranged than the latter instrument by the motion of a ship at sea, it follows that, in these respects, it possesses great advantages as a marine barometer in indicating the approach of gales of wind.

M. Pouillet, in the 7th edition of his 'Éléments de Physique,' 1856, gives a description of M. Bunten's sympiesometer. It is formed of an alcohol-thermometer, and an air-tube curved and open at its upper end. The reservoir of the air-tube is in the interior of the cistern of the thermometer, and completely surrounded by alcohol. The lower part of the reservoir and air-tube contains a column of oil of almonds, acted on by atmospheric pressure, so that the temperature of the air is always indicated approximately by the alcohol-thermometer. This temperature remaining constant, if the pressure is increased, the oil will descend in the open branch, and will rise if it be diminished. Similarly, if the pressure be constant, the oil rises or falls in the open branch, according to the temperature.

With respect to the proper hours of the day for observation, these, as Professor Daniell remarks, are indicated by the barometer. "The maximum height of the mercurial column is about 9 A.M., the mean at 12, and the minimum at 3 P.M. If a person have time to make three observations in the day, these are the hours which he should select; if circumstances only allow of his observing twice, 9 A.M and 9 P.M. are the proper periods; if only once, noon is the time. These, fortunately happen to be, probably, the most universally convenient hours that could have been selected. In national observatories it would not be too much to expect that observations at 3 P.M. should be added to the preceding. Even those who merely consult the barometer as a weather-glass, would find it an advantage to attend to these hours; for I have remarked, that by much the safest prognostications from this instrument may be formed from observing when the mercury is inclined to move contrary to its periodical course. If the column rise between 9 A.M. and 3 P.M., it indicates fine weather; if it fall from 3 to 9, rain may be expected." This subject is fully entered into in books on meteorology. We may especially refer to a paper on Meteorology, by Sir John Herschel, in the 'Admiralty Manual of Scientific Enquiry,' and also to a paper in the same work on Atmospheric Waves and Barometric Curves, by W. R. Birt, Esq.

Some interesting barometrical and meteorological observations have recently been made during four balloon ascents, made by Mr. Welsh, under the direction of the Kew Observatory Committee of the British Association, the results of which are published in the 'Philosophical Transactions' for 1853. These ascents were made in the latter part of 1852, and the objects especially aimed at were the determination of the temperature and hygrometric condition of the air at different heights, analysis of the air, and examination of the light reflected from the upper surface of the clouds. The barometer used was of Gay-Lussac's form (No. 14), Regnault's condensing, and Daniell's dew-point hygrometer. When about 3000 or 4000 feet above the upper surface of the clouds, they were examined with a polariscope. The light reflected from the clouds *next* the sun gave no trace of polarisation, while those on the side *from* the sun gave very slight traces, the light of the sky being all the time strongly polarised. The height above the level of the sea attained by the balloon was deduced from the barometric readings by Laplace's formula expressed in English feet and Fahrenheit's degrees:—

$$z = \log\left(\frac{h}{h'}\right) \times 60159\left(1 + \frac{t + t' - 64}{900}\right)\left(1 + 0{\cdot}002837 \cos 2\,\mathrm{L}\right)\left(1 + \frac{z + 52251}{20886900}\right).$$

z = height required; h and h'; t and t' = height of barometer and temperature at lower and upper station, L = latitude.

The observers mounted to more than 13,000, 18,000, 19,000, and in the last ascent to 22,370 feet, by which ascent the temperature fell from 49° to nearly —10°, and the dew-point fell from 37° to 12°. The temperature of the air decreased uniformly on ascending, but not continuously. At a certain height, varying on the different days, the decrease was arrested, and for 2000 or 3000 feet, the temperature decreased but little, or even increased, in ascending. Above this, the diminution again went on at nearly the same rate as in the lower region. This interruption was also accompanied by a sudden fall in the dew-point, or by an actual condensation of vapour. This region is the *region of the clouds*, and the increase of heat appears to arise from the latent heat liberated when aqueous vapour is formed into clouds. Dr. Miller, of King's College, analysed the samples of air collected at the various heights, and found scarcely any sensible variation in its composition with regard to the nitrogen and oxygen, but the samples were too small to allow of a *quantitative* examination for carbonic acid.

The *following rules* are given by Mr. J. H. Belville, of the Royal Observatory, Greenwich, in the third edition of his excellent little 'Manual of the Barometer,' London, 1858. He calls them "Phænomena of the Barometer."

Strong winds in the winter from the west, with a steady high pressure, invariably bring a high temperature and very little rain; with winds from the east, a low temperature and sharp frosts.

If the mercury fall during a high wind from the south-west, south-south-west, or west-south-west, an increasing storm is probable; if the fall be rapid, the wind will be violent, but of short duration; if the fall be slow, the wind will be less violent, but of longer continuance; the disturbing cause is probably the same in each case, but its intensity unequal; nearly all our high winds from the south-west come with a falling barometer.

If the depression of the mercury be sudden and considerable with the wind due west, a violent storm may be expected from the north-west or north, during which the mercury will rise to its former height. If the mercury fall with the wind at north-west or north, a great reduction of temperature will follow; in the winter severe frosts, in the summer cold rains.

A steady and considerable fall of the mercury during an east wind denotes that the wind will soon go round to the south, unless a heavy fall of rain or snow immediately follow; in this case the *upper* clouds usually come up from the south. The deep snow of the severe winter of 1814 was a notable instance.

The lowest depressions occur with the wind at south and south-east, when much rain falls, and frequently, short and severe gales blow from these points. In the winter months, sudden depressions of the mercury with the wind in these quarters are attended with electrical phenomena.

A fall of the mercury with a south wind is invariably followed by rain in greater or less quantities.

A falling barometer with the wind at north, brings the worst weather; in the summer, rain and storm will follow; in the winter and spring, deep snows and severe frosts. This case is of rare occurrence.

A great depression of the mercury during a frosty period brings on a thaw; if the wind be south or south-east, the thaw will continue; if the wind be south-west, the frost will be likely to return with a rising barometer and northerly wind.

In the winter season, a rapid rise of the mercury immediately after a gale from the south-west with rain (the wind going round to north-west or north) is usually attended with clear sky and sharp white frosts.

Great depressions in the summer months are attended with storms of wind and rain with thunder and hail; cold unseasonable weather generally succeeds these depressions.

During a period of broken cold weather in the winter months with the wind at north or north-north-west, a sudden rise of the mercury denotes the approach of rain and a southerly wind; thaws also commonly set in during the night.

During a steady frost with the wind at north, north-east, or east, a continued slow rising of the mercury indicates snow and cloudy weather.

If the mercury rise with the wind at south-west, south, or even south-east, the temperature is generally high.

Observation does not show that *extremes of temperature* are contemporaneous with the greatest elevations and least depression of the mercurial column.

Meteors are not prevalent during very low pressures; the *aurora borealis* has been noticed at all heights of the barometer. Small flashes of lightning are of frequent occurrence during stormy weather in the winter season when the mercury stands low.

Great elevations in the summer are generally attended with dry warm weather.

Great depressions at all seasons are followed by change of wind and by much rain.

A rising barometer with a southerly wind is usually followed by fine weather. In the summer it is dry and warm; in the winter, dry with moderate frosts. This is of rare occurrence.

When the mercury is very unsteady during calm, rainy weather, it denotes that the air is in an electrical state, and that thunder will follow.

In the summer months, if a depression of two- or three-tenths of the mercury occur in a hot period, it is attended with rain and thunder, and succeeded by a cool atmosphere. Sometimes heavy thunderstorms take place overhead without any fall of the mercury; in this case reduction of temperature does not usually follow.

Rain in some quantity may fall with a high pressure, provided the wind be in any of the northerly points; and when much rain falls with a steady rising barometer and the mercury attains a great elevation, a long period of fine weather usually succeeds.

If, after a storm of wind and rain, the mercury remain steady at the point to which it had fallen, serene weather may follow without a change of wind; but on the rising of the mercury, rain and a change of wind may be expected. During a series of stormy weather the mercury is in constant agitation, falling and rising twice or thrice in the space of twenty-four hours, the wind changing alternately from south to west, and backing again to the south; this alternation of winds continues until the mercury rises to a bold elevation, when it ceases and the weather becomes settled.

Storms of wind, especially when accompanied with much rain, produce the greatest depressions of the mercury. No storm of wind on record has blown without some rain falling, although the time of its falling and its amount have been variable; sometimes the rain has increased with the increasing storm and sinking mercury; at other times the rain has fallen suddenly at the close of the storm, or at the time of the *minimum* pressure.

No great storm ever sets in with a steady rising barometer.

As far as regards the locality of Greenwich, the most violent gusts of wind come from due south, and those next in violence from due north; in both instances, the mercury is stationary at its *minimum* point during the greatest *horizontal pressure*; the winds from these quarters are of short duration, and limited in their extent. The ordinary south-west gales will blow unremittingly for twenty-four hours, and will sweep over the whole of the British Isles.

Note.—Although a rising mercury attends a northerly wind, great depressions occur previously to a great storm coming from that quarter.

In England, the winds which blow for the greatest number of days together without intermission, are the west and west-south-west: they blow chiefly during the winter months, and are the principal cause of our mild winters.

The east, and east-north-east, are the winds the next most prevalent. The great antagonist winds, the north and south, are the origin of our most violent storms.

The westerly winds surge mostly by night, and their average force is twice that of the easterly winds.

The easterly winds are generally calm at night, but blow with some power during the day.

On an average, sunrise and sunset are the periods of the twenty-four hours in which there is the least wind. An hour or two after noon is the period when the wind is the highest.

As a general rule, when the wind turns against the sun, or *retrogrades* from west to south, it is attended with a falling mercury; when it goes in the *same direction* as the sun, or turns direct from west to north, the mercury rises, and there is a probability of fine weather.

It never hails in calm weather. When hail falls, it is during sudden gusts of wind, and the mercury rises while the hail is actually falling.

If the weather during harvest time has been generally fine, and a fall of the mercury with a shower occur—if the wind turn a few points to the north, and the barometer rises above 30 inches,—the weather may be expected to be fair for some days.

The finest and most beneficial state of the atmosphere, more especially as regards the health of man, is with a uniform pressure at a mean height of the climate varying from 29·80 to 30·00.

When there is only one current of air subsisting in the atmosphere, there is seldom much variation in the height of the mercurial column. It is when two or more *strata* of the air are in motion in different directions at the same time, that great fluctuations of the mercury occur.

In high pressures, the *upper* current usually sets from the northward; in low pressures it sets from the south and south-west.

The variations of the barometer are always greater in the winter than in the summer.

In accounting for the different currents of the atmosphere, it must be remarked that the great heat of the torrid zone causes a constant ascent of air over it, which passes northward and southward; while an under current of cold air flows from the poles to supply its place; the diurnal rotation of the earth, combined with these currents, causes the trade-winds, whose direction is from east to west: these currents would from the same causes become in the north temperate zone south-east and north-west winds; but the great irregularities of the temperature from the seasons, the large tracts of ocean, and the different geographical formations of the land, subject them to interruptions, and give to every country its prevailing winds, derived from local causes. In England the south-south-west, south-west, and west-south-west winds set in towards the end of October, and blow with their greatest strength during November, December, and February, and are even powerful in June and July; the winds from the westerly quarters prevail in March, but they then veer more towards the north, whence they blow with greater violence; in April, the east and north-east, and the west and north-west winds balance each other, and their comparative strength is nearly equal; in May, the east, north-east, and north-north-east winds preponderate; the latter blows the less frequently, but with the greatest violence; in that month the average of the winds from the westerly quarters ranges low; their average strength also decreases, with the exception of that from the west-south-west, which ranges higher than in April. In August, the west and west-south-west winds prevail, but their power is moderate; the stormy winds of this month blow from the west-south-west and north-north-west. September is the calmest period of the year; in the month the north and south winds, and the east and west winds, balance each other; in January, the east and west winds upon an average are nearly equal, both as regards the number of times they blow, and their average strength; the winds from the south-south-west, west-south-west, and the north-westerly quarters are more rare, but they blow with great violence. As the winds from these opposite quarters predominate, so is the character of our winters determined as to mildness or severity.

Sudden depressions of the barometer sometimes occur in weather apparently calm. It is almost an established fact that storms have a circular motion; and if, when an exhaustion or sudden diminution of the atmosphere takes place, the mercurial column happen to be in the partial vacuum or centre of motion, the air will be at rest; while the surrounding air at a greater distance from the centre will be violently agitated with a less fall of the barometer. This circular motion of the atmosphere is not confined to one spot where the storm may commence and expend its violence, but it has a progressive cycloidal movement onwards, changing constantly the situation of its centre of motion, and, as it advances, enlarging its circumference, until, having traversed many hundred miles, it becomes exhausted, as the air recovers its equilibrium. These great rarefactions of the atmosphere are probably the effects of electricity; they are common in their most terrific form in the Indian Ocean, on the western coast of Africa, and in the West Indies.

In our own climate the approach of thunder-clouds produces violent squalls of wind; and dense and highly electrified clouds will sometimes raise miniature whirlwinds as they pass overhead.

BARON, BARONY. Sir Henry Spelman (*Glossarium*, 1626, in voce *Baro*) regards the word *baron* as a corruption of the Latin *vir*: but it is a distict Latin word, used by Cicero, for instance, and the supposition of corruption is therefore unnecessary. The Spanish word *varon*, and the Portuguese *barão*, are slightly varied forms. The radical parts of *vir* and *baro* are probably the same, *b* and *v* being convertible letters, as we observe in the forms of various words. The word *barones* (also written *berones*) first occurs, as far as we know, in the book entitled 'De Bello Alexandrino' (cap. 53), where barones are mentioned among the guards of Cassius Longinus in Spain; and the word may possibly be of native Spanish or Gallic origin. The Roman writers, Cicero and Persius, use the word *baro* in a disparaging sense; but this may not have been the primary signification of the word, which might simply mean *man*.

But the word had acquired a restricted sense before its introduction into England, and probably it would not be easy to find any use of it in English affairs, in which it denoted the whole male population, but rather some particular class, and that an eminent class.

Of these by far the most important is the class of persons who held lands of a superior by military and other honourable services, and who were bound to attendance in the courts of that superior to do homage, and to assist in the various business transacted there. The proper designation of these persons was the Barons. A few instances selected from many will be sufficient to prove this point. Spelman quotes from the 'Book of Ramsey' a writ of King Henry I., in which he speaks of the barons of the honour of Ramsey. In the earliest of the Pipe Rolls in the Exchequer, which belongs to the thirty-first year of King Henry I., there is mention of the barons of Blithe, meaning the great tenants of the lord of that honour, now called the honour of Tickhill. Selden ('Titles of Honour,' 4to. edit., p. 275) quotes a charter of William, Earl of Gloucester, in the time of Henry II., which is addressed "Dapifero suo et omnibus baronibus suis et hominibus Francis et Anglis," meaning the persons who held lands of him. The court itself in which these tenants had to perform their services is called to this day the Court-Baron, more correctly the Court of the Barons, the Curia Baronum.

What these barons were to the earls, and other eminent persons whose lands they held, that the earls and those eminent persons were to the king: that is, as the earls and bishops, and other great landowners, to use a modern expression, had beneath them a number of persons holding portions of their lands for certain services to be rendered in the field or in the court, so the lands which those earls and great people possessed were held by them of the king, to whom they had in return certain services to perform of precisely the same kind with those which they exacted from their tenants; and as those enants were barons to them, so were they barons to the king. But, inasmuch as these persons were, both in property and in dignity, superior to the persons who were but barons to them, the term became almost exclusively, in common language, applied to them; and when we read of the barons in the early history of the Norman kings of England, we are to understand the persons who held lands immediately of the king, and had certain services to perform in return.

Few things are of more importance to those who would understand the early history and institutions of England, than to obtain a clear idea of what is meant by the word baron, as it appears in the writers on the affairs of the first two centuries and a half after the Conquest. They were *the tenants in chief of the crown*. But to make this more intelligible, we may observe that, after the Conquest, there was an actual and fictitious assumption of absolute property in the whole territory of England by the king. The few exceptions in peculiar circumstances need not here be noticed. The king, thus in possession, granted out the greatest portion of the soil within a few years after the death of Harold and his own establishment on the throne. The persons to whom he made these grants were, 1. The great ecclesiastics, the prelates, and the heads of the monastic institutions, whom probably, in most instances, he only allowed to retain, under a different species of tenure, what had been settled upon them by Saxon piety; 2. A few Saxons, or native Englishmen, who, in a few rare instances, were allowed to possess lands under the new Norman master; 3. Foreigners, chiefly Normans, persons who had accompanied the king in his expedition and assisted him in obtaining the throne: these were by far the most numerous class of the Conqueror's beneficiaries. Before the fourteenth or fifteenth year of his reign the distribution of the lands of England had been carried nearly to the full extent to which it was designed to carry it: for the king meant to retain in his own hands considerable tracts of land, either to form chaces or parks for field-sports, to yield to him a certain annual revenue in money, to be as farms for the provision of his own household, or to be a reserve-fund, out of which hereafter to reward services which might be rendered to him. These lands formed the demesne of the crown, and are what are now meant when we speak of the ancient demesne of the crown.

When this was done, a survey was taken of the whole: first of the demesne lands of the king; and next of the lands which had been granted out to the ecclesiastical corporations, or to the private persons who had received portions of land by the gift of the king. At the same time, the commissioners, to whom the making of this survey was entrusted, were instructed to inquire into the privileges of cities and boroughs, a subject with which we have not at present any concern. The result of this survey was entered of record in the book which has since obtained the name of 'Domesday Book,' the most august as well as the most ancient record of the realm, and for the early date, the extent, variety, and importance of the information which it contains, unrivalled, it is believed, by any record of any other nation. We see there *who* the people were to whom the king had granted out his lands, and at the same time *what* lands each of those people held. It presents us with a view, which is nearly complete, of the persons who in the first twenty years after the Conquest formed the barons of England, and of the lands which they held; the progenitors of those who, in subsequent times, wrested from the crown the different charters of liberties, and confined the kingly authority of England within narrower limits than those which circumscribed the regal power in most of the other states of Europe.

The Indexes which have been prepared to 'Domesday Book,' present us with the names of about 400 persons who held lands immediately of the king. Some of these were exceedingly small tenures, and merged at an early period in greater, or, through forfeitures or other circumstances, were resumed by the crown. On the other hand, 'Domesday Book' does not present us with a complete account of the whole tenancies in chief because—1. The four northern counties are, for some reason not at present understood, omitted in the survey; and 2. There was a creation of new tenancies going on after the date of the survey, by the grants of the Conqueror or his sons of portions of the reserved demesne. The frequent rebellions, and the unsettled state in which the public affairs of England were in the first century after the Conquest, occasioned many resumptions and great fluctuations, so that it is not possible to fix upon any particular period, and to say what was precisely the number of tenancies in chief held by private persons; but the number, before they were broken up when they had to be divided among co-heiresses, may be taken, perhaps, on a rude computation, at about 350. In this the ecclesiastical persons who held lands in chief are not included.

When we speak of the king having *given* or *granted* these lands to the persons who held them, we are not to understand it as an absolute gift for which nothing was expected in return. In proportion to the extent and value of the lands given services were to be rendered, or money paid, not in the form of an annual rent, but as casual payments, which the king had a right, under certain circumstances, to demand. The services were of two kinds: first, military service, that is, every one of those tenants (*tenants* from *teneo*, to hold) was bound to give personal service to the king in his wars, and to bring with him to the royal army a certain quota of men, corresponding in number to the extent and value of his lands; and, secondly, civil services, which were of various kinds, sometimes to perform certain offices in the king's household, to execute certain duties on the day of his coronation, to keep a certain number of horses, hounds, or hawks for the king's use, and the like. But, besides these honourable services, they were bound to personal attendance in the king's court when the king should please to summon them, to do homage to him (*homage* from *homo*, to acknowledge themselves to be his *homines*, or *barones*), and to assist in the administration of justice, and in the transaction of other business which was done in the court of the king.

We see in this the rude beginnings of the modern Parliaments, assemblies in which the barons are so important a constituent. But before we enter on that part of the subject, it is proper to observe, that among the great tenants of the crown there was much diversity both of rank and property. We shall pass over the bishops and other ecclesiastics, only observing, that when it is said that the bishops have seats in Parliament in virtue of the baronies attached to their sees, the meaning of the expression is, that they sit there as other lay homagers or barons of the king, as being among the persons who held lands of the crown by the services above mentioned; which is correct as far as Parliament is regarded as a court for the administration of justice, but doubtful so far as it is an assembly of wise men to advise the king in matters touching the affairs of the realm. Amongst the other tenants, we find some to whose names the word *vicecomes* is annexed. On this little has been said by the writers on English dignities; and the title *viscount* can scarcely have been used in 'Domesday' as an hereditary title, but more probably as a title of office answering to the present *sheriff*. There is indeed no reason to believe that this title was an hereditary dignity in this country before the reign of Henry VI. The office of sheriff in some counties was hereditary, but it was not a title of nobility. Some we find in 'Domesday' who have indisputably a title, in the proper sense of the word, annexed to their names, and which we know to have descended to their posterity. These are the *comites* of 'Domesday Book,' where, by the Latin word *comes*, they have represented the *earl* of the Saxon times; and as these persons were raised above the other tenants in dignity, so were they, for the most part, distinguished by the greater extent of the lands held by them. Among those to whose names no mark of distinction is annexed, there was also great diversity in respect of the extent of territory granted to them. Some had lands far exceeding the extent of entire counties, while others had but a single parish or township, or, in the language introduced at the Conquest, but a single manor, or two adjacent manors, granted to them.

All these persons, the earls included, were the barons, or formed the baronage, of England. Whether the tenancy were large or small, they were all equally bound to render their service in his court when the king called upon them. The diversity of the extent of the tenure affords a plausible discriminatory circumstance between two classes of persons who appear in early documents—the greater and the lesser barons; but a better explanation of this distinction may be given. In the larger tenancies, the persons who held them granted out portions to be held of them by other parties upon the same terms on which they held of the king. As they had to furnish a quota of men when the king called upon them, so they required their tenants to furnish men equipped for military service proportionate to the extent of the lands which they held, when the king called upon them. As they had to perform civil services of various kinds for the king, so they appointed certain services of the same kind to be performed by their tenants to themselves. As they had to do homage from time to time to the king, and to attend in his court for the administration of justice and for other business touching the common interest, so they required the presence of their tenants to acknowledge their subjection and to assist in the administration of that portion of public justice which the sovereign power allowed the great tenants to administer. The castles, the ruins of which exist in so many parts of the country, were the seats of these great tenants, where they held their courts, received the homage, and administered justice, and were to the surrounding homagers what Westminster Hall, a part of the court of the early kings of England, was to the tenantry in chief. The Earl of Chester is said to have thus subinfeudated to only eight persons the vast extent of territory which the Conqueror granted to him. These vassals had accordingly each very large tracts, and they formed, with four superiors of religious houses, the court, or, as it is sometimes called, the Parliament of the earls of Chester, and are frequently called the barons of that earldom. These persons were for the most part persons of Norman origin, the personal attendants, it may be presumed, of the great tenant. There is no authentic register of them, as there is of the tenants in chief; but the names of many of them may be collected from the charters of their chief lords, to which they were in most instances the witnesses. These, it is thought, constitute the class of persons who are meant by the lesser barons, when that term is used by writers who aim at precision.

Whether these tenants, or vassals of the crown vassals, had right of seat and vote in the great council of the king, is another and a difficult question. The proceedings of the Council of Northampton, in 1164, as stated by Fitz Stephen, lend some colour to the notion of two classes of barons being there present. But it may be doubted whether such a distinction as that here hinted at can justify the expressions "barones majores" and "barones minores," for unless all tenants in capite by knight's service are to be deemed "barones," there is little, if any authority in ancient documents for assuming the existence of the "barones minores" as a recognised class in the councils of the realm.

Many of what we have called (following popular usage) the lesser barons, or barons of the barons, became the progenitors of families of pre-eminent rank and consequence in the country. For instance, the posterity of Nigellus, the baron of Halton, one of the eight of the county of Chester, through the unexpected extinction of the male posterity of Ilbert de Laci, one of the greatest of the tenants in chief beneath the dignity of an earl, and whose castle of Pontefract, though in ruins, still shows the rank and importance of its early owners, became possessed of the great tenancy of the Lacis, assumed that name as the hereditary distinction, married an heiress of the earls of Lincoln, and so acquired that earldom; and when at length they ended in a female heiress, she was married to Thomas, son of Edmund, earl of Lancaster, son of King Henry III. The ranks indeed of the tenants in chief, or greater barons, were replenished from the class of the lesser barons; as in the course of nature cases arose in which there was only female issue to inherit. But even their own tenancies were sometimes so extensive, that they were enabled to exhibit a miniature representation of the state and court of their chief: they granted lands to be held of themselves; had their tenants doing suit and service; and, in point of fact, many of the smaller manors at the present day are but tenures under the lesser barons, who held of the greater barons, who held of the king. The process of subinfeudation was checked by a wise statute of King Edward I., who introduced many salutary reforms, passed in the 18th year of his reign, commonly called the statute *Quia Emptores, &c.*, which directed that all persons thus taking lands should hold them, not of the person who granted them, but of the superior, of whom the granter himself held.

The precise amount and precise nature of the services which the king had a right to require from his barons in his court, is a point on which there seems not to be very accurate notions in some of the writers who have treated on this subject; and a similar want of precision is discernible in the attempt at explaining how to the great court baron of the king were attracted the functions which belonged to the deliberative assembly of the Saxon kings, and the *Commune Concilium* of the realm, the existence of which is recognised in charters of some of the earliest Norman sovereigns. The fact however seems to be admitted by all who have attended to this subject, that the same persons who were bound to suit and service in the king's court constituted those assemblies which are called by the name of Parliaments, so frequently mentioned by all our early chroniclers, in which there were deliberations on affairs touching the common interest, and where the power was vested of imposing levies of money to be applied to the public service. It is a subject of great regret to all who wish to see through what processes and changes the great institutions of the country have become what we now see them, that the number of public records which have descended to us from the first hundred and fifty years after the Conquest is so exceedingly small, and that those which remain afford so little information respecting this most interesting point of inquiry.

There is however no reasonable doubt, that the Parliament of the early Norman kings did consist originally of the persons who were bound to service in the king's court by the tenure of their lands. But when we come to the reign of King Edward I., and obtain some precise information respecting the individuals who sat in Parliament, we do not find that they were the whole body of the then existing tenantry in chief, but rather a selection from that body, and that there were among those who came by the king's summons, and not by the election and deputation of the people, some who did not hold tenancies in chief at all. To account for this, it has been the generally received opinion, that the increase of the number of the tenants in chief (for when a fee fell among co-heiresses it increased the number of such tenants) rendered it inconvenient to admit the whole, and especially those whose tenancies were sometimes only the fraction of the fraction of the fee originally granted; and that the barons and the king, through a sense of mutual convenience, agreed to dispense with the attendance of some of the smaller tenants. Others have referred the change to the latter years of the reign of King Henry III.; when the king, having broken the strength of the barons at the battle of Evesham, established a principle of selection, summoning only those among the barons whom he found most devoted to his interest. It is matter of just surprise, that points of such importance as these in the constitutional history of the country should be left to conjecture; and especially, as from time to time claims are presented to Parliament by persons who assert a right to sit there as being barons by tenure,—that is, persons who hold lands immediately of the king, and whose ancestors, it is alleged, sat by virtue of such tenure. The committee of the House of Lords, which sat during several sessions of Parliament to collect from chronicle, record, and journal everything which could be found touching the dignity of a peer of the realm, made a very voluminous and very instructive report in 1819. This has been followed by reports on the same subject by other committees. They all confess that great obscurity rests upon the original constitution of Parliament, and suppose the probability that there may still be found among the unexamined records of the realm something which may clear away at least a portion of the obscurity which rests upon it. To us it appears that the principle of selection above alluded to, which probably was admitted from the very earliest period, and from the time of Edward I. was adopted as a part of the constitutional system, is the only theory upon which the existence of an hereditary nobility, such as that presented by the House of Lords, can be explained. The right of barons by tenure to sit in the House may be justified on the assumption that upon the first institution of Parliament, as now constituted, the selection made by the king was exercised purely and solely on the ground of tenure of some particular castle or barony, whilst in other cases it was merely personal and irrespective of tenure.

We are now arrived at a time when the word *baron* acquired a sense still more restricted than that which has hitherto belonged to it. Later than the reign of Edward II. we seldom find the word *baron* used in the chronicles to designate the whole of that formidable body who were next in dignity to the king himself, who formed his army and his legislative assembly, and who forced the monarch to yield points of liberty either to themselves as a class, or to the whole community of Englishmen. The counts or earls, from this time, stand out more prominently as a distinct order. There were next introduced into that assembly persons under the denomination of dukes, marquesses, and viscounts; to all of whom was given a precedence before those barons who had not any dignity, strictly so called, annexed to the service which they had to render in Parliament. The baron became the lowest denomination in the assembly of peers, possessing the same rights of discussing and voting with any other member of the house, but remaining destitute of those honorary titles and distinctions the possession of which entitled others to step before him. The term also ceased to be applied to those persons who, possessing a tenancy in chief, were not yet summoned by the king to attend the Parliament; and the right or duty of attendance, from the time of King Edward I., has been founded, not, as anciently, upon the tenure, but on the writ which the king issued commanding their attendance.

Out of this has arisen the expression *barons by writ*. The king issued his writ to certain persons to attend in Parliament, and the production of that writ constituted their right to sit and vote there. Copies of these writs were taken, and are entered on what is called the close roll at the Tower. The earliest are in the latter part of the reign of King Henry III., in the forty-ninth of his reign, when the king was a prisoner in the hands of Simon de Montfort, who did what he pleased in the king's name. There are many such writs existing in the copies taken of them, of the reign of Edward I., and all subsequent kings, down to the present time. They are addressed to the archbishops and bishops, the prior of Saint John of Jerusalem, many abbots and priors, the earls and peers of the higher dignities as they were introduced into the peerage, and to a number of persons by their names only; as William de Vescy, Henry de Cobham, Ralph Fitzwilliam, William la Zouch, and the like; portions of the baronage whom the king chose to call to his councils. Upon this the question arises, whether when a person who was a baron by tenure received the king's writ to repair to the Parliament, the receipt of the writ, and obedience to it, created in him a dignity as a lord of Parliament which adhered to him during his life, and was transmitted to his heir. Upon this question the received opinion undoubtedly has been, that a heritable dignity was created; that once a baron, by sitting under authority of the king's writ, always a baron; and that the barony would endure as long as there were heirs of the body of the person to whom the king's writ had issued. Upon this, the received opinion, there have been many adjudications of claims to dignities, and yet the Lords' committee on this subject express very strong doubts respecting the doctrine, and contend that there are persons to whom the king's writ issued, and who took their seat accordingly, to whose heirs similar writs never went forth, though there was no bar from nonage, fatuity, or attainder. On the other hand, there is the strong fact, that we do find, by the writs of summons, that they were addressed to the several members of many of the great families of England, as they rose in successive generations to be the heads of their houses: that, when it happened that a female heiress occurred, her issue was not unfrequently set in the place in Parliament which her ancestors had occupied; and that when the new mode arose in the time of Richard II., of creating barons by patent, in which a right was acknowledged in the posterity of the person so created, the ancient barons who had sat by virtue of the king's writ to them and their ancestors did not apply for any ratification of their dignity by patent, which they would have done had they not conceived that it was a heritable dignity, as secure as that granted by the king's patent.

The doubt of the Lords' committee, however, shows that this is one of the many points touching the baron on which there is room for question. The practice, however, has been hitherto to admit that proof of the issuing of the writ, and of obedience to it, by taking a seat in Parliament, or what is technically called proof of sitting, entitles the person who is heir of the body of a person so summoned to take his seat in Parliament in the place which his ancestor occupied.

In interpreting the phrase *heir of the body*, the analogy of the descent of corporeal hereditaments in the feudal times is followed. That is, if a person die seised of the dignity of baron, and leave a brother and an only child, a daughter, the daughter shall inherit in preference to the brother, though the dignity has been transmitted from some person who is ancestor to them both. This fact clearly shows how close a connection there is between the dignity and the lands, the descent of both being regulated by the same principle. The consequence of this principle is, that through a portion of the baronage there has been an introduction of new families into the peerage without the sanction of the crown; for the heiress of one of these baronies may now bestow herself in marriage at her pleasure; and though it is not held that the husband can claim the benefit of the tenancy by courtesy principle (though doubts have been entertained on this point), yet, the issue of the husband may undoubtedly, whoever he may be, take his place in Parliament in the seat which his mother would have occupied had she been a male. Practically, the effect of this upon the composition of the House of Peers has been very small indeed.

The case of co-heiresses demands a distinct notice, because it will lead to the explanation of a phrase which is often used by persons who seem not to have very distinct notions concerning what is implied by it. Lands may be divided, but a dignity is by its very nature indivisible. Thus, if the representative of one of the ancient barons of Parliament die, leaving four daughters and no son, his lands may be divided in equal portions among them, and would be so divided according to the principle of the feudal system. But the dignity could not be divided; and as the principle of that system was against any distinction among co-heiresses (reserving the occurrence in the course of nature of persons dying leaving no son but several daughters, to be the means of preventing the too great accumulation of lands in the same person, and of breaking up from time to time the great tenancies), it made no provision that either the *caput baroniæ*, or a dignity that was indivisible, should descend to the eldest, or any daughter in preference to her sisters. It therefore fell into *abeyance*. [ABEYANCE.] It was not extinguished or destroyed, but it lay in a sort of silent partition among the sisters; and in this dormant, but not dead state, it lay among the posterity of the sisters. But if three of the four died without leaving issue, or if after a few generations the issue of three of them became utterly extinct, the barony would then revive, and the surviving sister, if alive, or the next heir of her body, would become entitled to the dignity, and might, on proof of the necessary facts, claim a writ of summons as if there had been no suspension. Again, it is a part of the royal prerogative to *determine an abeyance*; that is, the king may select one of the daughters, and give to her the place, state, and precedency which belonged to her father; and then the barony will descend to the several heirs in succession of her body, as entire as if there had never been any state of abeyance. But this does not interfere with the rights of the other co-heirs, who, and whose posterity, remain in precisely the same position in which they stood before the king determined the abeyance in favour of a particular branch. In this way the barony of Clifford, which has several times fallen into abeyance, was, in our own time, given to a co-heir. The same was the case with the baronies of Ross and Berners, and indeed it is in a great measure to the exercise of this prerogative of the crown that we owe the presence in the House of Peers of barons who take their seats at the head of the bench, and date their sittings from the 14th and 13th centuries.

The principle of the feudal law, which was favourable to the claims of females, was fraught with ruin to noble houses. The great family which springs from Hugh Capet, and a few other great families of the Continent, have had the address to escape from the operation of the principle by availing themselves of what is called the Salic law; and to this is owing that they still hold the rank in which we now see them, a thousand years after they first became illustrious. This must have been early perceived in England, and it was probably this consideration which led to the introduction of a class of barons, the descent of whose dignity should not be regulated by the principle of the feudal descent of hereditaments, but should be united inseparably with the male line of persons issuing from the stock of the original grantee. This innovation is believed to have first taken place in the reign of King Richard II., who in his eleventh year created John Beauchamp of Holt a baron, not merely by writ of summons to Parliament, but by a patent, in which it was declared that he was advanced to the state, style, and dignity of a baron, and that the same state, style, and dignity should descend to the *male heirs* of his body. Thus and at this time the class of *barons by patent* arose. The precedent thus set was, with very few exceptions, followed in the subsequent reigns; and by far the great majority of persons who now occupy the barons' bench in Parliament are the male representatives of persons on whom the dignity has been conferred, accompanied by a patent, which directs the course of its descent to be in the male heirs for the time being of the original grantee. Should it ever happen that they are exhausted, the dignity becomes extinct.

It has been reserved for our own times to settle one other very important question with respect to the baronage, namely, whether the grant of the dignity of baron *for life* only, entitles the holder to sit in the House of Peers. This was determined in the negative, in the case of Lord Wensleydale, in the session of 1855-56. It would be equally out of place here either to state the arguments in support of, or in opposition to, the view taken by the House of Lords in this case, or to express the general opinion of lawyers on the subject. The result of the decision has been to call attention to the mode of acquiring, and to the disabilities consequent on attaining, the peerage, and to raise much discussion as to the expediency of having some recognised life-peerages, similar in their nature, though different in their object, to the life baronies of the bishops. It is unnecessary to enter into any examination of the privileges of the barons, which in no respect differ from those of the other component parts of the House of Peers. [PEERS OF THE REALM.]

The principal writers upon the subject of this article are, John Selden, in his work entitled 'Titles of Honour,' first published in 1614; Sir Henry Spelman, in his work entitled 'Archæologus, in modum Glossarii,' folio, 1626; Sir William Dugdale, in his 'Baronage of England,' 3 volumes folio, 1675 and 1676; and in his 'Perfect Copy of all Summonses of the Nobility to the Great Councils and Parliament of this Realm, from the 49th of Henry III., until these present times,' folio, 1685; 'Proceedings, Precedents, and Arguments on Claims and Controversies concerning Baronies by Writ, and other Honours,' by Arthur Collins, Esq., folio, 1734; 'A Treatise on the Origin and Nature of Dignities or Titles of Honour,' by William Cruise, 8vo., 2nd edit., 1823; 'Report on the Proceedings on the Claim to the Barony of Lisle, in the House of Lords,' by Sir N. H. Nicolas, 8vo., 1829. But the most complete, though not always correct, information on this subject is contained in the printed 'Report from the Lords' Committees, appointed to search the Journals of the House, and Rolls of Parliament, and other Records and Documents, for all matters touching the Dignity of a Peer of the Realm.'

The word *Barony* is used in the preceding article only in its sense of a dignity inherent in a person: but the ancient law-writers speak of persons holding lands by *barony*, which means by the service of attending the king in his courts as barons. The research of the Lords' Committees has not enabled them to trace out any specific distinction between what is called a tenure by barony and a tenure by military and other services incident to a tenancy in chief. The Hiltons in the North, who held by barony, have been frequently called the Barons of Hilton; but whether in virtue of their territorial barony, or of their summons to Parliament, it is difficult to say. They received writs of summons to Parliament, and sittings can be shown in more than one instance under such writs. A peerage of Parliament has therefore been created, descendible to the heir general of the body of the person first summoned, namely, Robert de Hilton, temp. Edw. I., and is now in abeyance between the co-heirs of the Baron of Hilton who sat last in Parliament. Burford, in Shropshire, is also called a barony, and its former lords, the Cornwalls, who were an illegitimate branch of the royal house of England, were called, in instruments of authority, Barons of Burford, but they never had a summons to Parliament, nor privilege of peerage. *Barony* is also sometimes, but rarely, used in England for the lands which form the tenancy of a baron, and especially when the baron has any kind of territorial addition to his name taken from the place, and is not summoned merely by his christian and surname. This seems, however, to be done rather in common parlance than as if it were one of the established local designations of the country. The *head of a barony* (*caput baroniæ*) is, however, an acknowledged and well-defined term. It designates the castle or chief house of the baron, the place in which his courts were held, where the services of his tenants were rendered, and where, in fact, he resided. The castles of England were heads of baronies, and there was this peculiarity respecting them,—that they could not be put in dower, and that if it happened that the lands were to be partitioned among co-heiresses, the head of the barony was not to be dismembered, but to pass entire to some one of the sisters.

Barony is used in Ireland for a subdivision of the counties, equivalent to what is meant by hundred or wapentake in England.

It remains to notice a few peculiar uses of the word baron:—

1. The chief citizens of London, York, and of some other places in which the citizens possess peculiar franchises, are called in early charters not unfrequently by the name of '*the barons*' of the place. This may arise either from the circumstance of the persons only being intended who were the chief men of the place; or that they were, in fact, barons, homagers of the king, bound to certain suit and service to the king, as it is known the citizens of London were and still are.

2. The *Barons of the Cinque Ports* are so called, probably for the same reason that the citizens of London and of other privileged places are so called. The Cinque Ports, which were Hastings, Dover, Hythe, Romney, and Sandwich (to which afterwards Rye and Winchelsea were added), being ports opposite to France, were regarded by the early kings as places of great importance, and were consequently put under a peculiar governance, and endowed with peculiar privileges. The freemen of these ports were barons of the king, and they had the service imposed upon them of bearing the canopy over the head of the king on the day of his coronation. Here was the feudal service which marked them as persons falling within the limits of the king's barons. Those sent of themselves to Parliament, though sitting in the lower house, might be expected to retain their appellation of barons.

3. Those persons who held lands in the island of Bute, in Scotland, directly of the Marquis of Bute, the crown vassal, have long been called Barons of Bute; a designation analogous probably in its origin to the Barons of Chester.

4. The *Barons of the Exchequer*. The judges in that court are so called, one of them being the *Chief Baron*. The court was instituted immediately after the Conquest, and it is probable that the judges were so denominated from the beginning. They are called barons in the earliest Exchequer record, namely, the Pipe Roll of 31 Henry I. [EXCHEQUER.]

BA'RONAGE. This term is used, not so much to describe the collective body of the barons in the restricted sense which now belongs to the word, as signifying a component part of the hereditary nobility of England, but the whole of that nobility taken collectively, without regard to the distinction of dukes, marquesses, earls, viscounts, and barons, all of whom form what is now sometimes called the baronage.

In this sense the term is used in the title of one of the most important works in the whole range of English historical literature, for the sake of giving a short notice of which, we have introduced an article under this word. We allude to 'The Baronage of England,' by Sir William Dugdale, who was the Norroy King at Arms, and one of the last survivors of those eminent antiquarian scholars who, in the 17th century, raised so high the reputation of England for that particular species of learning.

Sir William Dugdale was the author of many other works, but his history of the baronage of England is the one to which reference is more frequently made; and there is this peculiarity belonging to his labours, that the Baronage is quoted by all subsequent writers as a book of the highest authority; and it has, in fact, proved a great reservoir of information concerning the families who, from the beginning, have formed the baronage of England, from which all later writers have drawn freely.

The first volume was published in 1675; the second and third, which form together a volume not so large as the first, in 1676. The work professes to contain an account of all the families who had been at any period barons by tenure, barons by writ of summons, or barons by patent, together with all other families who had enjoyed titles of higher dignity, beginning with the earl of the Saxon times.

It was an undertaking of infinite labour, but Dugdale was an indefatigable man. Nothing like it had before appeared. Accounts of the higher orders of the English nobility had been given before his time in the works of Milles, Brooke, and Vincent, but these accounts are excessively meagre, scarcely, in any instance, going beyond the statement of genealogical particulars, or the most prominent facts in the lives of the persons who had held those dignities. But Sir William Dugdale has collected from the chronicles, from the chartularies of religious houses, with which he became acquainted while preparing his great work on the history of the monasteries, from the rolls of Parliament, in his time only to be perused in manuscript, and from the public records, which he could consult only in the public repositories, or in the extracts made from them by his fellow-labourers in historical research, and finally from the wills in the various ecclesiastical offices throughout the kingdom, the particulars of the lives of the most eminent men of our nation. Without pretending to the graces of language, and with the introduction of less of political or moral reflection than perhaps might be desired, he has produced a work which is not only rich beyond precedent in the most authentic information, but which is read with interest and pleasure by all persons who have any tincture of the spirit of historical inquiry. But while he has thus clothed and almost animated the dry figures of the earlier writers on the higher nobility of the realm, the accounts which he has given of the persons who form the lower class, the barons, in the stricter sense, whether by tenure, writ, or patent, are entirely his own. Nothing before his time had been done to collect their names, to show their origin, or to display their illustrious achievements. This part of his work, that is, by far the larger portion of it, is pre-eminently his own; and the best tribute to its excellence is the fact to which we have alluded above, that his accounts of these illustrious persons are considered, by all subsequent writers, as genuine and authentic as if he stood in the position of a contemporary chronicler, and that so few persons have since arisen who have shown themselves able to make any addition of much value to the accounts which he has left.

Not the least merit of the work is the careful reference to authorities, which renders it a most valuable book, not only to the student in the family antiquities of the English nation,—not only to those who are delighted to read of the eminent persons of the English nation in the days of chivalry, in the times of the Crusades, and in the wars with France and Scotland,—but to the practical man, who undertakes to prosecute claims to baronies or other dignities, of which there is always one or more before Parliament, and who finds here the reference to the documents which it is necessary to produce in the prosecution of such claims.

This work contains some defects in respect of the general plan, in which we find no sound criterion by which to determine the claims to admission among those who are called barons by tenure. The arrangement also admits of much improvement, and there are occasionally mistakes and misrepresentations in the minuter details. Still nothing has yet superseded it; but he who shall undertake the work of re-modelling, correcting, improving, and continuing it to the present day, will enter on his duty with advantages which his predecessor did not enjoy. Some of the chief authorities on which Dugdale relied have been printed by the Board of Commissioners on the Public Records, and are now easily accessible to the historical inquirer, who formerly was obliged to be content with slight inspections in the offices in which the originals are deposited, or to depend on transcripts which might not always be exact.

One passage in the preface to the Baronage contains a striking truth: "As this historical discourse will afford at a distance some, though but dim, prospect of the magnificence and grandeur wherein the most ancient and noble families of England did heretofore live, so will it briefly manifest how short, uncertain, and transient earthly greatness is; for of no less than two hundred and seventy in number, touching which this first volume doth take notice, there will hardly be found above eight which do to this day continue; and of those not any whose estates, compared with what their ancestors enjoyed, are not a little diminished; nor of that number, I mean two hundred and seventy, above twenty-four who are by any younger male branch descended from them, for aught I can discover."

BARONET, an English name of dignity, which in its etymology imports a Little Baron. But we must not confound it with the lesser baron of the middle ages [BARON], with which the rank of baronet has nothing in common; nor again with the banneret of those ages [BANNERET]; though it does appear that in some printed books, and even in contemporary manuscripts, the state and dignity of a banneret is sometimes called the state and dignity of a baronet, by a mere error, as Selden asserts ('Titles of Honour,' p. 354), of the scribe.

The origin of this rank and order of persons is quite independent of any previous rank or order of English society. It originated with James I., who, being in want of money for the benefit of the province of Ulster in Ireland, hit upon the expedient of creating this new dignity, and required of all who received it the contribution of a sum of money, as much as would support thirty infantry for three years, which was estimated at 1095*l.*, to be expended in settling and improving the province of Ulster.

The principle of this new dignity was to give rank, precedence, and title without privilege. He who was made a baronet still remained a commoner. He acquired no new exemption or right to take his seat in any assembly in which he might not before have been seated. What he did acquire we can best collect from the terms of the patent which the king granted to all who accepted the honour, to them and the heirs male of their bodies for ever: 1. Precedence in all commissions, writs, companies, &c., before all knights, including knights of the bath and bannerets, except such knights banneret as were made in the field, the king being present; 2. Precedence for the wives of the baronet to follow the precedence granted to the husband; 3. Precedence to the daughters and younger sons of the baronet, before the daughters and younger sons of any other person of whom the baronet himself took precedence; 4. The style and addition of *Baronet* to be written at the end of his name with the prefix of *Sir*; 5. The wife of the baronet to be styled *Lady*, *Madam*, or *Dame*. It was stipulated on the part of the king, that the number of baronets should never exceed two hundred; and that, when the number was diminished by the natural process of extinction of families, there should be no new creations to supply the places of those extinct, but that the number should go on decreasing. Several baronets are nevertheless created every year. Further, the king bound himself not to create any new order which should lie between the baron and the baronet.

Another distinction was soon after granted to them. A question arose respecting precedency between the newly created baronets and the younger sons of viscounts and barons, which the king disposed of by his own authority, in favour of the latter; and in the same instrument in which he declared the royal pleasure in this point, he directed that the baronets might bear, either on a canton or in an escutcheon on their shield of arms, the arms of Ulster, which, symbolical it seems of the lawless character of the inhabitants of that province, as is set forth in the preamble of the baronet's patent, was a bloody hand, or in the language of heraldry, a hand gules in a field argent. And further, the king "to ampliate his favour, this dignity being of his majesty's own creation, and the work of his hands," did grant that every baronet, when he had attained the age of twenty-one years, might claim from the king the honour of knighthood (a privilege entirely obsolete); that in armies they should have place near about the royal standard; and lastly, that in their funeral pomp they should have two assistants of the body, a principal mourner, and four assistants to him, being a mean betwixt a baron and a knight.

BARONY. [BARON.]

BAROSCOPE, the *perceiver of weight*, is a term which has sometimes been applied to the barometer. It may, however, be well applied to all such barometers as, from badness in their principles or construction, show a change of the air's weight, without furnishing any good means of measuring it. Such are the conical and Hooke's barometer. The human body is sometimes, to a certain extent, a baroscope.

BARRACK, originally a hut or little lodge for soldiers in a camp from the Spanish *barracas*, meaning small cabins, such as fishermen build upon the sea-coast. Temporary constructions of this sort for the horse were formerly called *barracks*; those for the foot, *huts*; the word barrack was afterwards indifferently used for both. Barracks of this description are generally made by fixing four forked poles in the ground, and laying four others across them; the walls being afterwards built up with sods, wattles, or what the place may afford, and the top planked, thatched, or covered with turf. Modern camps, especially for winter quarters, are often formed of such barracks arranged in streets.

The word barrack does not occur in our older dictionaries, though it is found in Phillips's 'World of Words,' fol., London, 1706. Barrack, in a more enlarged sense, is now applied to the permanent, and commodious buildings, in which both officers and men are lodged in fortified towns or other places.

A writer in a periodical paper entitled 'Common Sense,' No. 105, published in 1739, speaks of permanent barracks for the lodging of troops as then just introduced. He states that a few years before, in 1720, when the plague raged at Marseille, an attempt was made to raise such buildings in London, under pretence that if we should be visited, the sick might be removed to them. But the design was seen through; the citizens took the alarm, and cried out they would have no *red-coat-nurses*.

Great opposition was made in parliament, during the French revolutionary war, to the erection of barracks on an extended scale, as inimical to the liberties of the country, as calculated to estrange the soldier from the citizen, and to render the former a fit tool to enslave the latter, should the people be called upon to submit to unpopular or arbitrary measures. Other arguments had greater weight, however, on the side of these establishments: the system of quartering was, in many instances, vexatious; the morals of a country town or village were corrupted proportionally as soldiers were quartered upon the inhabitants; and it was found that soldiers and citizens might be too much, as well as too little, intermixed.

Until the middle of the reign of George III., barracks of this last description were not numerous in Great Britain. When wanted, they were built under the direction of the Board of Ordnance, by whom they were supplied with bedding and utensils; but the articles which were extraordinary were under the management of the secretary-at-war. This system prevailed until the middle of 1792, when the situation of public affairs induced his majesty's ministers to give orders to build, with the utmost dispatch, cavalry barracks in various parts of the kingdom; and Colonel de Lancey, then deputy-adjutant-general, was requested to undertake the arrangement of the business. In January, 1793, he was appointed superintendent-general of barracks, and on the 1st of May that year the king's warrant was issued for their regulation. More extensive authority was given to him by a warrant dated May 30th, 1794, when he was appointed to the office of barrack-master-general to the forces. But as this seemed to interfere with the duties and powers of the Board of Ordnance, a new warrant was issued in 1795, defining the powers of the barrack-master-general, and those of the Board of Ordnance; under which warrant Lieutenant-General De Lancey acted in all subsequent transactions. The salaries and extra pay of the barrack-master-general and his officers amounted, in 1796, to 9524*l.* 17*s.* 2*d.* The establishment was afterwards considerably increased, in proportion as the number of barracks throughout the kingdom multiplied, and by the creation of new officers. In March, 1806, their salaries amounted to 19,329*l.* 4*s.* 10*d.*

During this year, the commissioners of military inquiry recommended that the offices of barrack-master-general and deputy barrack-master-general should be totally abolished, and that the superintendence of the barrack establishment should be vested in commissioners. This suggestion, with some others relative to the mode of transacting the business of the department, and preventing useless and extravagant expenditure, were followed, and the barrack establishment placed under the direction of four commissioners, one of whom was generally a military man.

On the late Duke of Wellington becoming Master-general of the Ordnance, and Commander-in-Chief of the Forces, forty years ago, great changes and improvements were introduced into the barrack department. It was wholly re-organised and placed under the Board of Ordnance. The barracks themselves were placed immediately under the management and care of the resident barrack-master, who had charge of all articles supplied by the barrack-office, such as beds, bedding, sheets, blankets, house and stable utensils, coals and candles, an allowance of money being made in lieu of beer which was formerly supplied by the barrack-master. The head of this barrack branch was a member of the board. The charge of execution of all barrack building and repairs, was transferred to the corps of Royal Engineers, their head, the Inspector-General of Fortifications being also a member of the board.

In 1855, the Board of Ordnance was done away with, and the civil portion of the barrack department placed under the War Office, the executive being still retained by the Royal Engineers, under the Inspector-General of Fortifications, with a particular staff for that purpose, at Whitehall.

The building and repairs are usually performed by contract, under the supervision of the Royal Engineer Department; Great Britain and Ireland being divided for this purpose into the following districts, each district under the charge of a Commanding Royal Engineer, with a staff of Royal Engineers, and civil branch of clerks and foremen of works, under him: Camp at Aldershot, Woolwich, Dover, London, Newcastle, Harwich, Chatham, Sheerness, Exeter, Portland, Pembroke, Birmingham, Manchester, York, Portsmouth, Devonport, Jersey, Guernsey, Edinburgh, Dublin, Belfast, Cork, Limerick, and Curragh Camp. Abroad, at all places where troops are stationed, these duties are performed in the same manner.

Great improvements have at various times been made in the comfort and accommodation of barracks, but more especially when the late Duke of Wellington became Master-General of the Ordnance. When the barrack departments were transferred to the Ordnance, the men were placed in wooden sloping berths ranged in two tiers, two men slept in the same bed, and the subaltern officers were placed two in a room. The first improvement was substituting single iron bedsteads for the wooden berths, and then allotting a certain number of cubical feet for each man in a room—450 to 500 feet in a temperate climate, and 600 to 700 feet for hospitals; 480 to 600 feet in a tropical climate, and 700 to 900 feet for hospitals;—and the construction of cooking and ablution rooms, with an ample supply of water for the men to cook in barracks. The second improvement was the establishment of a sergeants' mess, appropriating quarters to staff sergeants, &c., and the construction of ball courts for recreation. These were carried out at considerable expense, though, some of the barracks being old, very imperfectly. In all new barracks that were built, much more attention was paid to the comfort of the soldier. There was still, however, great room for improvement, and in 1857, a Royal Commission, of which the Right Hon. Sidney Herbert was chairman, having recommended many alterations, and obtained grants of money for experiments in ventilation, &c., they are being carried out at the present time. In the new cavalry barracks at Aldershot, each man has 1000 cubic feet of room. Great attention is being paid to the ventilation of barracks—the improvement of cooking apparatus—ablution and bath rooms with hot and cold water—the establishment of libraries and reading rooms, and all that can tend to the health and comfort of the soldier. According to the present regulation field officers are allowed two rooms and a kitchen each; captains and subalterns one room each; regimental staff, according to their relative ranks; staff-sergeants and married sergeants one room each; unmarried sergeants one room between two. Two rooms are allowed for the officers' mess, and one room for sergeants'. Separate quarters are being built for married men; and rooms set apart as reading rooms and libraries. A War Office circular of 1858 lays down 600 cubic feet as the minimum barrack space, and 1200 as the minimum hospital space for each man; also that day rooms for meals are very desirable, and to be provided in future. 24 or 12 men, as forming sections or half sections of a company, are allotted to each room.

The total expenditure in Great Britain and the islands of Guernsey, Jersey, and Alderney, on buildings for the purposes of barracks from 1793 to November 10th, 1804, was 4,115,383*l.* 6*s.* 1¾*d.* The total expenditure in Great Britain and Ireland, on buildings for the same purposes (including the artillery), from 11th November, 1804, to 24th December, 1819, was 3,220,857*l.* 17*s.* 5*d.* Expenditure from 1793 to 1819, in buildings in Great Britain for the purposes of barracks for the artillery, 735,842*l.* 3*s.* 3*d.* The estimates for barrack building and repairs were, in 1858-59,—588,370*l.* at home, and 76,959*l.* abroad. The grant to the Barrack and Hospital Improvement Commission in the same year was 57,000*l.*, and 100*l.* for each barrack in the kingdom. The estimates for 1859-60 were 726,841*l.* for barracks at home, and 70,281*l.* for barracks abroad. The above, it must be remembered, are the estimates only, large sums of which are often not expended, but revoted or not the next year according to circumstances.

(*Reports of Commissioners of Military Inquiry into Management of the Military Departments* (*Fortification and Barracks*), session 1811 (122), xlii.; *Report of Select Committee to consider the subject of Barracks*, session 54—55 (Lords), 314, 314a, xxvi.)

BARRATRY, BARATRY, or BARRETRY. The original derivation of this word is extremely uncertain: in English law it has a twofold signification, which it is difficult to trace from any account yet given of its etymology. First, barratry is a misdemeanor at common law, and consists in frequently exciting and stirring up disputes and quarrels by litigation; and secondly, it denotes a fraud committed by the master or mariners of a ship with relation to the ship or cargo, by which the owners or freighters may be injured. The Italian word *barratrare*, from which the term barratry in this latter sense is immediately derived, means *to cheat* generally; but in English law it is entirely a technical expression, and is only used to denote that particular description of knavery above described.

I. As to the misdemeanor of barratry at common law.

This offence is so indefinite in its nature, and has been so little noticed in modern times, that it would probably be found difficult at the present day to prosecute a barrator to conviction. Sir Edward Coke and other authorities state that it is not necessary, in order to constitute the offence, that the suits promoted by the barrator should be commenced in courts of record; the offence may be committed by stirring up litigation in hundred or county courts, or other inferior jurisdictions. It is also said not to be a material part of the offence that the suits or quarrels commenced should relate to a disputed title to the possession of lands, but that all kinds of disturbances of the peace and the dispersion of false rumours and calumnies which may promote discord among neighbours will amount to barratry. A single act cannot amount to barratry, as the essence of the crime consists in the frequent repetition of acts tending to stir up quarrels; nor is it necessary that an indictment for this offence should specify any particular transactions in which the person accused has promoted contention or litigation, it is said to be sufficient to state generally in the indictment that he is a *common barrator*, thus leaving the whole matter to the jury. This anomaly in criminal law, from which it would follow that a defendant might be called upon at the trial to justify fifty distinct and complicated transactions without the slightest previous notice, necessarily led to another, namely, that the prosecutor is bound to deliver to the defendant before trial a notice of the particular acts on which he means to insist, and it is, of course, a rule that none can be given in evidence but such as are stated. The punishment for this offence is fine and imprisonment, at the discretion of the court; but Mr. Serjeant Hawkins says, that "if the offender be of any profession relating to the law, he ought to be disabled from practising in future." ('Pleas of the Crown,' book i. c. 81.) At common law, it appears that a person convicted of barratry might have been sentenced to the pillory. In the case of the King against the Warden of the Fleet ('Mod. Rep.' xii. 340), the record of the punishment of a barrator by a fine being produced, Lord Holt said, "If he had had the handling of him, he had not escaped the pillory; and that he remembered Serjeant Maynard used to say that it were better for the country to be rid of one barrator than of twenty highwaymen." By stat. 12 Geo. I. c. 29, (made perpetual by 21 Geo. II. c. 3), "if any person convicted of common barratry shall practise as an attorney, solicitor, or agent in any suit or action, the court shall, upon complaint or information, examine the matter in a summary way; and if it shall appear that the person complained of has offended, shall cause the offender to be transported for seven years." There is no recorded instance of proceedings having ever been taken under this statute. Under this head may be mentioned another offence of equal magnitude, that of suing in the name of a fictitious plaintiff. This offence is a high contempt of court; and punishable in the superior courts at their discretion. In inferior courts the stat. 8 Eliz. c. 2, directs the punishment to be six months imprisonment, and treble damages to the party injured.

II. Barratry by masters or mariners of ships.

This offence is not an object of the criminal law of England; and in this country is only a subject of importance with reference to maritime insurances. From the earliest times, a loss by the barratry of the master or mariners has formed a subject of indemnity by underwriters in British policies of insurance. The absurdity and impolicy of inserting this species of loss in marine policies have often been pointed out by high authority. "It is somewhat extraordinary," says Lord Mansfield in the case of *Nutt* v. *Bourdein* ('Term Rep.' i. 330), "that this term should have crept into insurances, and still more that it should have continued in them so long, for the underwriter insures the conduct of the captain (whom he does not appoint, and cannot dismiss) to the owner, who can do either." Lord Ellenborough makes the same remark, and also points out the impolitic tendency of this kind of insurance, as enabling the master and owners, by a fraudulent and secret understanding, to throw upon the underwriters the failure of an illegal adventure, of which the benefit, if successful, would have belonged solely to themselves. (*Earle* v. *Rowcroft*, East's 'Rep.,' viii. 134.) Upon this it may, however, be observed, that merchants are always desirous to limit the number of their risks as much as possible; and if they are willing to pay for their indemnity from the fraudulent acts of their own servants, there seems to be nothing unreasonable in such a contract; while, on the other hand, it is the whole business of underwriters to insure against risks, and it is quite indifferent to them what the nature of that risk is, provided they clearly understand the nature of it, and receive a proportionate premium.

The legal meaning of the term barratry thus inserted in policies of insurance has frequently become a subject of discussion in courts of justice. Its original and verbal signification is framed in the most general sense, and is defined in Dufresne's 'Glossary' as "fraus, dolus, qui fit in contractibus et venditionibus," without being limited to marine contracts, or to any particular class of contracting parties. In English law, however, it is certainly understood only in the limited sense mentioned in the commencement of this article. It means every species of fraud or knavery in the master or mariners of the ship by which the freighters or owners are injured. Barratry may therefore be committed either by a wilful deviation tending to defraud the owner, by smuggling, by running away with the ship, by sinking or deserting her, or by delaying the voyage by any means, or for any length of time, with a fraudulent intent. It follows, that in all cases where the underwriter has insured against barratry, the assured will be entitled to recover the amount of a loss which he may have sustained in consequence of any of the acts above enumerated. There must, however, be always a fraud or breach of trust in order to constitute barratry; and therefore a mere deviation in consequence of the ignorance of the master will not amount to barratry, though it would avoid the policy as being a variation from the voyage insured. It must also be an act done tending to defraud the owner, unless in itself criminal; and therefore where the owner consents to the acts done by the master, though they may amount to a gross fraud upon the underwriter, they will not constitute the technical offence of barratry; and, for the same reason, where the master of a ship is also the owner, there can be no barratry committed by him, because he cannot defraud himself. (Arnould, on 'Marine Insurance,' 2nd ed. vol. ii. p. 843.)

BARREL. The word barrel, or something equivalent, is found in several European languages, as denoting a large vessel for holding liquors. In the old English measures it was used to denote 31½ old gallons of wine, 32 of ale, or 36 of beer. The ale and beer barrels were equalized for every part of England except London, by a statute of the 1st of Will. & Mary, and 34 gallons were made the barrel of beer or ale. But the complexity still remained very great; for there were barrels containing diverse number of gallons, and gallons of diverse sizes. Thus, the wine gallon, by a statute of Anne, was declared to be 231 cubic inches, and the beer gallon (which did not differ from the ale gallon) was usually reckoned as 282 cubic inches; consequently the dimensions of the four barrels were as follow:—

	Gallons.	Cubic inches.
Wine barrel	31½	7316½
Ale ditto (London)	32	9024
Ale and beer ditto (England)	34	9518
Beer ditto (London)	36	10152

In imperial gallons of 277·274 cubic inches, now in use [GALLON], these measures are as follow:—

	Imp. gallons.
Old Wine barrel	26¼
„ Ale ditto (London)	32[illegible]
„ Ale and beer ditto (England)	34[illegible]
„ Beer ditto (London)	36[illegible]

Many other *barrels* were in use to denote certain quantities of goods usually sold in barrels; thus the barrel of salmon or eels was 42 gallons, that of soap 256 pounds, &c.

The measurement of the content of a barrel or ordinary cask may be done with sufficient exactness as follows, in which the curve of the staves is considered as a parabola:—Measure the diameter of the widest part (allowing for thickness) and that at the ends, which call the greater and smaller diameters: also measure the length from end to end. To the larger diameter add one-fourth of the smaller, and multiply this sum by itself. Multiply one-fourth of the smaller diameter by itself, and take the result five times. Add together the last two results; multiply the sum by the length of the barrel, and that product by ·41888. The product is the number of cubic *inches* in the barrel, if the lengths were measured in *inches*.

The word barrel is often applied, in common use, to any hollow cylinder, such as the barrel of a gun, a jack, or a hand-organ.

BARREL-DRAIN. [DRAIN.]

BARREL-ORGAN. [ORGAN.]

BARREN LAND, in agriculture, is that in which the plants generally cultivated do not prosper or arrive at maturity. This barrenness may arise from various causes. The texture of the soil may be such, that the moisture essential to vegetation cannot be retained, or that the fibres of the roots cannot penetrate in search of food. The first is the case in loose siliceous sands, the second in rocks and indurated clays. It is seldom that either of these soils can be rendered productive, so as to repay the expense of cultivation, unless under particular circumstances. The most barren sands will become productive by irrigation, and in that case the labour applied to improve their texture, by the admixture of more tenacious earth, may be fully repaid. The vine may be made to grow in the fissures of the hardest rocks, where the climate is favourable; and terraces may be formed, by which the soil brought on may be retained; but in general loose sands and rocks ought to be left to their natural state of barrenness.

There are, however, in all countries tracts of land which are barren and waste in their present state, and which, for want of better soils to employ and feed an increasing population, are well worth improving, and will ultimately repay the labour bestowed on them.

In 1829, it appears that the soil in the British dominions may be divided as follows: Taking the total surface of England, Wales, Scotland, Ireland, and the British islands, at 77,394,433 acres, only 46,522,970 acres were in cultivation, leaving 30,871,463 acres uncultivated, or nearly so. Some part of this, no doubt, consists of high sheep-walks, mountains, bogs, and water; but a large portion is capable of improvement, by the application of capital and industry.

Since that date, exact information has been obtained of many particulars regarding the average of the different conditions of land in the United Kingdom. [AGRICULTURAL STATISTICS.] Sheep-walks and drives, and waste lands attached to farms, amount, according to the figures for England, to nearly 3,000,000 of acres, and there are 3,800,000 acres unaccounted for. The statistics for Scotland, as ascertained by Mr. Hall Maxwell for the Highland Society, do not refer to sheep-walks, woods, and water. In Ireland, the unenclosed pastures amount to at least 8,000,000 acres, in addition to 4,000,000 or 5,000,000 capable of improvement.

Looking at these figures, it is impossible not to ask whether so very large a proportion of the surface of the British dominions in Europe may not remain uncultivated more from want of industry and skill than from insuperable barrenness.

We shall endeavour to give, as briefly as possible, an outline of the various means by which even the poorest soils may be rendered capable of adding something to the general stock of food necessary for a large and increasing population. The question as to the policy of cultivating such lands in preference to importing supplies of foreign grain, is not here considered. Our object is to show how barren lands may be improved, whenever such improvement may be deemed expedient.

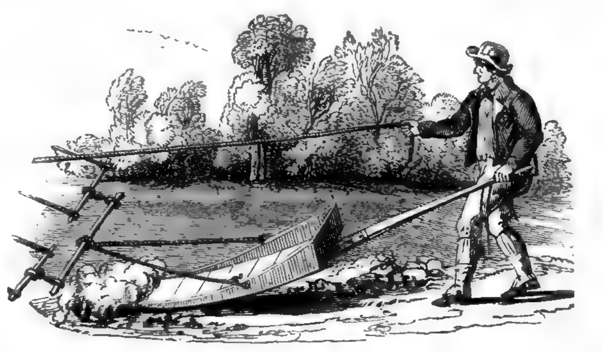
Some lands are barren in consequence of noxious ingredients in the soil, which by their chemical action on the food of plants, or on their minute fibres, prevent their growth and render them sickly and abortive. These, having been ascertained by careful analysis, must be deprived of their noxious qualities by chemical means, one of the most obvious of which is burning or baking. Nature has supplied a general and complete antidote to acid combinations, in lime, one of the most abundant of mineral productions. There are few bad soils which lime will not improve. The most common substances found in barren soils are different combinations of metals, principally iron, with sulphur and acids; quick-lime either decomposes all these or renders them innocuous. Another substance is *tannin*, or the astringent principle, which is of vegetable origin, and, by preventing the solubility of vegetable fibres, transforms them into an inflammable substance well known by the name of peat or moss. This, likewise, is readily corrected by the same means, and experience has proved that of all substances which can be obtained in sufficient quantities lime is the most valuable as an improver of bad soils. But the different substances of which a soil is composed may be perfectly innocuous to vegetation, and yet the barrenness may not be the less, if the supply or circulation of moisture be deficient or excessive. This must therefore be the first consideration, before any improvement is attempted; and if sufficient moisture cannot be supplied, or superfluous removed, all other attempts will only be lost labour. In tropical climates, irrigation is the chief source of fertility, and the most expensive works have been constructed, both in ancient and modern times, to supply the land with water as occasion requires. In northern and moister climates, the foundation of all improvements in the soil is a proper outlet to superfluous water. These two subjects will be treated in the articles IRRIGATION and DRAINING.

Supposing, then, that the moisture has been regulated, and that the land is to be brought into cultivation, the first thing to be done is to remove obstructions and impediments, whether they be rocks, stones, trees, or shrubs, or only the heath and coarse grasses which generally cover waste lands. Rocks may be quarried or blown, and so may stones too large to be removed whole, and the fragments will often be useful in building the necessary farm offices, or making fences to divide the land into fields of convenient dimensions, and especially to keep off animals from destroying the crops. A simple method of getting rid of large stones is to dig a deep hole by the side of them, as near as possible, and roll them in, so that they may be buried at least two feet below the surface. If they can be removed, this may be done by means of a common triangle with a windlass and pulley, raising them on a low carriage with broad wheels, such as is used for heavy timber. If the nature of the stones is lamellated, and they will split, wedges of soft iron driven into holes made in the direction of the layers readily divide them into flat pieces extremely convenient for use. A very powerful wedge for this purpose is an iron cylinder cut through the axis into two pieces, between which a thin iron or steel wedge is inserted: a hole is bored in the stone of a diameter equal to that of the cylinder, and when this cylinder and wedge are put into it, the wedge is driven in with repeated smart strokes of a hammer. Several such wedges, placed in a line, will split large masses of the hardest granite, and, next to gunpowder, are the most efficacious instruments for that purpose. Trees must be grubbed up by the roots, and it saves labour to cut the roots below the ground while the tree is standing, and draw the tree over by means of ropes fixed to the top; the stem becomes a lever, by which the roots are more easily drawn out. Useless shrubs are readily cut down, and serve for fuel; their roots are seldom difficult to grub up; a simple and powerful

instrument for this purpose is a very strong iron three-pronged fork, having the prongs 20 inches long, and a strong ashen handle, 20 feet long, fixed firmly into it, to the end of which a rope is fastened; this is driven obliquely under the roots, and by means of a log as a fulcrum it forms a lever when pulled down by the ropes.

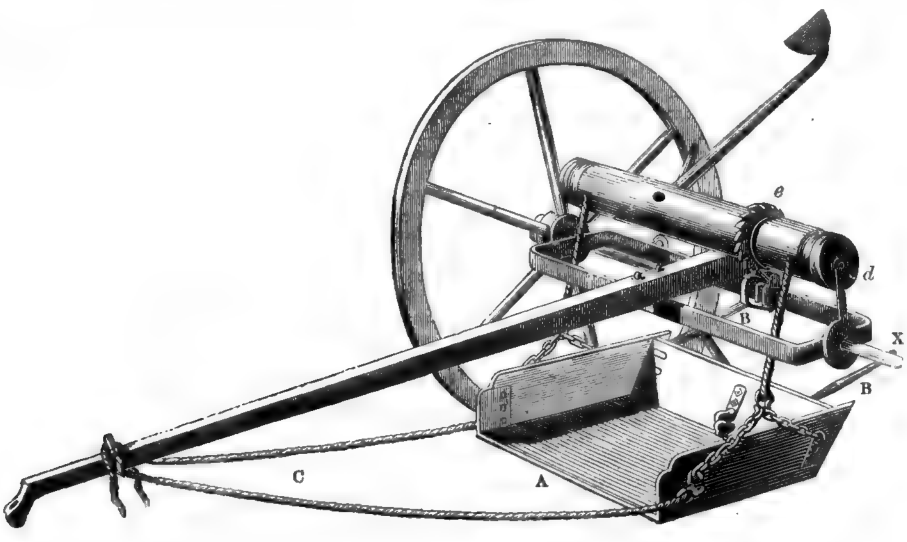
There are two methods by which the heath and grass of the surface may be got rid of, by mowing them close to the ground, and ploughing in the roots, or by paring the surface and burning it. Each mode has had its strenuous advocates, and has been alternately praised and reprobated. A little consideration will soon settle this point. If the soil consists of clay or loam containing yellow ferruginous earth, and if the ashes, after the sods have been burned in heaps, are of a bright red colour, the effect of burning the surface will be generally advantageous, even where the soil is already deficient in vegetable matter; for the fire will do more good in correcting the crude qualities of the soil, than the small quantity of vegetable matter which is dispersed would have done, had it been decomposed in the most favourable manner, and the tough roots of the heath which are reduced to ashes would have taken a very long time to decay, and would have been a constant impediment to the plough. But if the soil is a sharp sand, and the ashes are white and loose, burning destroys the small portion of clay and vegetable matter in the soil, without compensating the loss by any advantage, and in this case burning the surface is inexpedient. The roots of the heath must be grubbed up by spades and mattocks, or by means of a strong plough; they may then be gathered and burned, but the grass must be ploughed in, and not too deep at first that it may soon rot; a coating of lime ploughed in will accelerate the decay of the grass. This kind of soil requires the addition of vegetable and animal matter, and the principal attention must be directed to this object.

When the surface is very uneven, so as to form hillocks and hollows, in which the water is apt to stagnate, levelling is a necessary process. The most effectual way of doing this is by the wheelbarrow and shovel, provided the distance to which the earth is to be wheeled does not exceed a hundred yards. The surface should be first pared off, and put in heaps or rows, to be replaced when the operation of levelling has been performed, in order that the best earth, impregnated more or less with vegetable matter, may not be buried under the poorer subsoil. If the soil is loose and sandy, it may be very expeditiously levelled by an instrument in use in Flanders, which they call a *mollebart*. It is a large wooden shovel, shod with iron, having a long handle: about the middle of this shovel, which is convex at the bottom, are two hooks, one on each side, to which chains are fixed which unite at the bar to which the traces of a horse or horses are to be attached: a rope fixed to the end of the handle completes the instrument. A man accustomed to the use of it raises the handle, and the shovel enters the ground, and is filled by the horse going on. By depressing the handle, the load is made to slide on the rounded bottom of the shovel, till it arrives at the place where it is to be deposited. By letting the handle go, retaining the rope, the whole is upset instantly, turning over on the edge; the handle strikes on the bar, and the load is left behind in a heap. By pulling the rope, the whole



instrument resumes its original position, and is brought back to the place from which the earth is to be taken again, without any loss of time, or the slightest stoppage of the horses. About 5 cwts. of loose earth may be thus moved at each time. By means of this machine the small fields in Flanders are raised about two feet or more in the centre, and the ground laid convex, sloping in every direction to let the water run off. Thus also the soil of the headlands, which accumulates by the repeated turnings of the plough in our fields, might be carried back to the middle, or spread evenly over the ground. A patent has been lately obtained in France for an improved instrument of this kind, which has two large wheels for such grounds as will not readily allow the *mollebart* to slide over it. It is more complicated, but as it may afford useful suggestions, and be improved and simplified, we give a drawing and description of it.

A is the box or shovel to contain the earth, the bottom of which



opens to release the load; B B two handles; C ropes to keep the box steady; *d* a windlass, with *e* a ratched wheel to raise the box when full; X is the axle on which the second wheel runs, which has been taken off to show the construction of the instrument. It is not yet brought into general use, but the experiments made with it are said to have been quite satisfactory.

The land being now enclosed, fenced, and drained where requisite, obstacles to the plough removed, and in a tolerably level state, it remains only to consider how it may be most advantageously cultivated, so as in the end to repay the first and great outlay. Some lands which have lain waste for ages for want of a proper spirit of enterprise, are found to consist of a tolerable depth of moderately fertile earth. These must be treated like a garden newly formed, and trenched as deep as possible; mere exposure to the air and frost will often make them highly productive, and in this case the only caution necessary is not to exhaust them at first; on the contrary, their fertility should be increased by such crops and manuring as will always restore more humus than has been consumed by vegetation. It is too common an error with those who have made a great outlay, to be impatient, and expect too rapid a replacement of the capital laid out. This makes them sow white crops in preference to roots and legumes; and as fresh earth is generally very productive, especially in straw, they imagine the land to be of a better quality than it really is, and soon exhaust it, by which they lose infinitely more in the end than if they began with roots and green crops, and raised a quantity of manure by the stock fed on them. Lime excites new land wonderfully, and no manure is more active, provided there be vegetable matter in the soil or added at the same time. The lime renders the natural humus soluble and active, and, if put on injudiciously, will soon leave none for future crops. Bone-dust will raise a better crop of turnips than lime alone; but bone-dust, or, what is better, coarsely-bruised bones, are chiefly of use in raising the first crop of turnips. They should therefore be used sparingly, unless they can be obtained very cheap, and only on light loams or sands. Mixed with ashes in a heap, and allowed to heat, they become much more efficacious.

But after all the expense of clearing the land and preparing it for cultivation, it may yet be of such a quality as to dishearten the improver. We shall take an example from two kinds of soil very common in all the northern parts of Europe. The one is generally called sandy heath soil, the other is peat or moor, both quite unproductive till they are improved; and yet vast tracts of both have been brought into cultivation, and are covered with a rich harvest, in spite of their natural barrenness. Sir Humphry Davy declared, on analysis, that the soil of Bagshot Heath, in its natural state, was the most barren soil in England; yet great portions of this barren soil are now covered with thriving plantations, interspersed with green fields. The methods used to bring this land into cultivation will serve as an example for all similar soils. The surface soil of the heath consists of sand, gravel, and light loam, strongly impregnated with a yellow carbonate and sulphate of iron; the subsoil is generally a stiffer loam. The water which percolates the upper stratum dissolves a portion of the iron by means of the carbonic acid which rain water contains, and this iron, mixed with earth, is slowly deposited in a thin layer on the impervious subsoil, where it takes a hard crystallised form, called the *iron pan*, absolutely impervious to moisture; and until this pan be broken, no cultivation can take place. Trenching is, therefore, absolutely necessary wherever this pan exists at a small depth under the surface. A part of the subsoil being brought to the surface greatly improves the texture of the sand, and then the salts of iron must be decomposed and the acid neutralised by lime or chalk. Manure is now the principal object, and, if it cannot be obtained from neighbouring towns, or from old cultivated lands near at hand, the progress will be very slow. Planting trees, especially the fir and the larch, is then the only resource; but where manure and calcareous earth, either in the form of chalk, marl, or lime, can be obtained, the land may be cultivated and improved in the following manner: Lay on a good coating of chalk or marl before winter, and plough it in with a shallow furrow. In spring, plough again deeper, mixing the calcareous earth as much as possible with the soil by frequent harrowings: all the dung that can have been collected must be laid on and ploughed in by the end of May. In June, drill turnip-seed with bone-dust, if possible, in rows not too distant; say twelve inches, if the soil is very poor, but wider in proportion as it is of better quality. These, as soon as they are in the rough leaf, must be carefully hoed till they nearly cover the ground. They must be fed off by sheep in the following winter and spring: the dung of the sheep must be ploughed in with a shallow furrow as soon as possible after the sheep are removed. The quality of the first crop will decide whether a crop of corn may be ventured on in the second year, in which case tartarian oats are found the best suited to such land: but, if the turnips were not a very good crop, a second crop of the same, or of cole, for the sake of variety, to be again fed off, will be much better husbandry; and, until the soil shows an evident improvement in colour and texture, the most that can be expected is a crop of turnips and oats alternately. As soon as the ground has, by frequent tillage and manuring, become of a uniform and somewhat mellow texture, the first opportunity must be taken to lay it down with white clover and perennial grasses, and let it remain in pasture two or three years without mowing. When it is next broken up, it may be treated as the old cultivated lands of a similar quality usually are.

If a well-cultivated farm is near, and a sufficient supply of manure can be raised upon it, by converting a portion of it into artificial meadows, or keeping it under green crops, so that an increased quantity of stock may be maintained, the land to be improved may be soon brought into a productive state, without robbing the old land to make the new, as is too often done. Nothing has so rapid an effect in removing sterility as the free use of the urine of cattle, and the draining of dung-hills, collected and allowed to ferment in covered tanks; but this can only be obtained by keeping cattle stalled and fed with provender brought to them. This is the great secret of the fertility of the once poor barren heaths of Flanders. In different situations it may not be practicable to procure sufficient manure, at least at first, and the progress will be much slower. In this case the seeds of rye, tares, beans, buck-wheat, and other succulent plants, must be sown, and the crop ploughed in when in blossom; potatoes and other roots may be raised, to be consumed by cattle and swine, in sheds built for the purpose near at hand, and every means that ingenuity can devise must be resorted to in order to make as much manure as possible. This is not to be applied to the land at once, but mixed up in heaps with sods and parings of the surface, with the ashes of roots burned, and with lime, and when thoroughly incorporated by frequent turning, mixing, and repeated watering with liquid manure, a good coat should be put on the land at once, as far as it will go: for one acre brought into a tolerably fertile state will repay the cost better than many imperfectly improved; and by proceeding gradually in this way, more land will be brought into a state fit for cultivation at the end of a few years, and at less expense, than could have been done by beginning with too much at first.

When an attempt is made to bring a large extent of very poor sandy soil into cultivation at once, as may be the case where labour is cheap, it would be impossible to procure the requisite quantity of manure to ensure any return for the outlay. In that case there is a simple remedy, which, in the end, is very advantageous; it is, to sow the seeds of broom and furze, which will readily come up, and, in the course of two or three years, not only be of some value to cut for fuel for bakers, but in the mean time have greatly improved the nature of the soil, especially that which has been trenched, by the quantity of vegetable substance contained in the roots and their fibres, and also in the leaves and tender stems which have decayed and dropped during the three years that the land has been covered with these plants. This, at all events, will more than repay the interest of the money expended in trenching, and the future improvement will go on much more rapidly than if the ground had been treated as recommended above when first broken up. This practice also is taken from our sagacious and industrious neighbours the Flemish.

What has been said of a poor heath, or sandy loam, is applicable to every kind of unproductive soil, difference of composition and texture being kept in view. Poor, wet, stiff lands must be divided by deep ditches, ploughed in high ridges, and be as much as possible exposed to the wind and frost: instead of turnips, grasses must be sown, such as suit the soil. Paring and burning the surface are here generally useful in the first instance, and may sometimes be repeated with advantage. Such soils, in the end, are best calculated for permanent meadows; but it is essential to get them into a sound and fertile state by tillage and manuring, and by clearing them of all the roots and seeds of weeds before they be laid down with grass-seeds, which must therefore be done with a first crop after a clean fallow, or, which is still better, without any crop of corn at all, and kept free from coarser grasses by hand-weeding. [Grass.]

There is another kind of barren soil, which extends over large tracts in northern climates, well known by the name of peat, or moor. This, being chiefly composed of vegetable matter, is too loose in its texture for any vigorous vegetation. But, besides, it is of an insoluble, astringent nature, highly unfit for the increase and nourishment of plants. Moors being generally situated in valleys between mountains, draining off the superfluous water is the first and indispensable operation before any improvement of them can be thought of. The next thing is to compress the soft soil into a more solid state; and for this purpose any kind of earth or gravel is useful by its mere mechanical pressure. The surface may be burned in sods, and the ashes will greatly improve the remainder. Lime, chalk, marl, and shells are the specific correctors of the quality and texture. By the help of these, the soft mass, which can only be stirred with a spade by men standing on boards, is made to produce abundant crops of potatoes and oats; and, gradually condensing, a more compact soil is formed, which soon bears the tread of men and even cattle, and then, properly speaking, the cultivation may be said to begin. The great object is to prevent the absorption of too much moisture by the still unconsolidated mass, which is effected by cutting numerous and deep ditches in every direction, with proper outlets kept carefully open; at the same time guarding against the opposite extreme of drying this spongy substance too much. If it is dry at top, and moist, but not boggy, a foot below the surface, it will be in the best state to improve and consolidate. It is surprising how soon a peat moss, of little more solidity than a bog, can be rendered perfectly firm, and bear even loaded waggons on its surface. It often happens, where there is a command of good water which can be brought above the level of the old peat moss, that it may be converted into a most productive water-meadow. All that is required is, that the upper soil, artificially produced, be not broken through, and that the bottom be well drained.

We have only given brief hints and outlines to those who may be inclined to render lands productive which have hitherto been barren. The certain cost and probable improvement must be well calculated and compared to avoid disappointment and loss. As these depend on the peculiar circumstances of each case, it is impossible to give any general idea of them. But, by beginning on a small and experimental scale at first, and proceeding cautiously, new modes of lessening the expense of many of the operations will be suggested, errors will be avoided, and some certain practical ground of calculation will be obtained.

That there is a great pleasure in the pursuit no one can doubt, who sees at what expense favourite barren spots are improved; and a scanty harvest on land created, as it were, by art, pleases the proprietor more than the most abundant which his richest lands can produce.

Many a fortune, no doubt, has been impaired by rash speculations and too sanguine hopes; but, without this spirit of improvement, few soils, except the very richest, would ever have been cultivated, until the wants of a population greater than the richest lands could feed had forced the cultivation of those of inferior quality. It is in the tillage of very poor soils, chiefly, that those improvements in the utensils and operations of husbandry have been suggested and invented, without which a great portion of the soil of the British dominions, and of a considerable part of Europe, could never be cultivated to any advantage, much less afford rent to a proprietor, or contributions to the expenses of the nation.

The unproductive state of waste lands in many populous countries has suggested the employment of the poor and friendless on their improvement, and it has been thought a more enlightened charity to expend the money, which would otherwise be given in simple temporary relief, in such a manner as to make the labour of paupers available to their future comfort and independence. In some places portions of land have been given absolutely, or at a nominal rent, to paupers, in order that they might cultivate and gradually improve them; and where the soil is naturally good, and requires only to be worked and tilled, the plan has been attended with great success. But where a barren waste can only be improved by artificial manures and expensive operations, it is folly to expect this to be done by labour alone, without considerable capital; and neither the judicious managers of public funds nor prudent speculators on their own account will venture to lay out much capital on the chance and with the hope that a naturally indolent and idle class of men shall make it productive either to themselves or those who have advanced the funds.

A portion of good land, let at a fair rent to a poor family, with a little pecuniary assistance at first, in the purchase of a cow or pigs, and provisions, until the land produces food for the family, to be repaid by instalments, will occasion much less expense, and will in general be attended with less loss and fewer casualties than the improvement of poor sands and heaths, however judicious may be the management; and the ground converted into a garden will increase much more rapidly in value, than an equal quantity, originally worth nothing, can ever be made worth by three times the labour bestowed. Let the rich then be the improvers of wastes, and the poor lay out their surplus labour on more grateful soils.

It is near increasing manufactories, where land acquires a greater value, that barren land is soon converted into fertile fields. It is there, also, that the improvement of waste lands is most profitable, and the neighbourhoods of Aberdeen, Birmingham, Manchester, and Sheffield, among many others, furnish examples of the greatest industry and perseverance in overcoming the natural barrenness of the soil. Even Chat Moss, between Liverpool and Manchester, which was a few years back nothing but a quaking body of peat to a great depth, is covered with green fields and farm buildings.

BARRICADE. A military term, derived most probably from the verb to *bar*—its origin has been attributed to the French word *barriqué*, in allusion to the defences of the streets of Paris during the disturbances of the League, &c. It is applied either to the temporary obstruction to attack, made by the occupation and conversion of buildings into defensive posts in the field, or to the defences thrown up by either party during insurrectionary movements in towns; or occasionally to the barriers [BARRIER] which close the entrances of a fortress.

When of a permanent character, barricades are made with heavy pales or stakes, shod with iron. [STOCKADE.] Those of a temporary nature are constructed of anything that may happen to be at hand; carts and waggons, with their wheels taken off and filled with stones, baskets full of earth, trees, furniture, woolpacks, bales of cotton, have all been used. In Paris where, during the revolutionary outbreaks, barricades have played a most important part, the pavement of the street has generally furnished the material for them. The present Emperor of the French has had the whole of the pavement removed from the Boulevards and principal thoroughfares of Paris, the roadways macadamised, and the footpaths laid down in asphalte. Some years ago, in making arrangements for defence, in Ireland, moveable portions of palisading were constructed, which could be carried to any place where a barricade was required, put up in a few minutes, and made musket proof by a wall of sandbags on the inside.

(See *Royal Engineer's Aide-Mémoire*, art. 'Barricade.')

BARRIER, from the verb to *bar*, in a general sense, means any piece of wood-work or other construction which presents an obstacle to passing through the place where it is fixed: hence it comes to signify a fortification, or strong place, on the frontiers of a country. Thus we used formerly to speak of the barrier-fortresses of Flanders. It is likewise a kind of fence composed of stakes and transoms, or athwart rafters, erected to defend the entrance of a fortress or intrenchment, which, when musket proof, is called a stockade [STOCKADE], when simply obstructive, a palisade. In the middle of the barrier there is generally a very strong gate made of vertical wooden bars, about five feet long, kept together by two long bars across, and another diagonally. In field works the barrier is made of the strongest material procurable, but in permanent fortifications it is generally made with stockades and a heavy gate such as that described above. (*Royal Engineer's Aide-Mémoire*, art. 'Barrier and Gate.')

BARRIER TREATY. [TREATIES, CHRONOLOGICAL TABLE OF.]

BARRING-OUT, a practice formerly common in schools. Dr. Johnson, in his 'Life of Addison,' says, that in 1683, in the beginning of Addison's twelfth year, "his father being made dean of Lichfield, naturally carried his family to his new residence, and I believe placed him for some time, probably not long, under Mr. Shaw, then master of the school at Lichfield, father of the late Dr. Peter Shaw. Of this interval his biographers have given no account, and I know it only from a story of a *barring-out*, told me when I was a boy, by Andrew Corbet, of Shropshire, who had heard it from Mr. Pigot, his uncle. The practice of barring-out," he adds, "was a savage licence practised in many schools at the end of the last century, by which the boys, when the periodical vacation drew near, growing petulant at the approach of liberty, some days before the time of regular recess, took possession of the school, of which they barred the doors, and bade their master defiance from the windows. It is not easy to suppose that on such occasions the master would do more than laugh; yet, if tradition may be credited, he often struggled hard to force or surprise the garrison. The master, when Pigot was a schoolboy, was barred out at Lichfield, and the whole operation, as he said, was planned and conducted by Addison."

Brand, in his 'Popular Antiquities,' vol. i. pp. 346, 347, speaks of the custom as still existing in the grammar-school of the city of Durham, and at the school at Houghton-le-Spring. It no longer exists.

In the statutes of Witton School, near Northwich, in Cheshire, founded by Sir John Deane in 1558, the observance of this practice by the scholars is directed. (See Carlisle's 'Description of Endowed Grammar Schools,' vol. i. p. 133.) It prevailed long also at Rothbury, near Alnwick, in Northumberland. (Ibid. vol. ii. p. 259.) An entertaining story of a barring-out is given in vol. vi. of Miss Edgeworth's 'Parent's Assistant,' 12mo. Lond. 1813. Hutchinson, in his 'History of Cumberland,' vol. ii. p. 322, says this custom was used by the scholars of the free-school of Bromfield in that county, about the beginning of Lent, or, in the more expressive phraseology of the country, at Fasting's even.

BARRISTER. The etymology of this word has been variously given by different authors, and it would be unprofitable to enumerate the fanciful derivations which have been assigned to it. But, though the precise etymology of the term is uncertain, there is little doubt that it arose from the local arrangement of the halls of the different Inns of Court, which for several centuries have composed in England a kind of university for the education of advocates. [INNS OF COURT.] The benchers and readers, being the superiors of each house, occupied on public occasions of assembly the upper end of the hall, which was raised on a *dais*, and separated from the rest of the building by a bar. The next in degree were the *utter* barristers, who, after they had attained a certain standing, were called from the body of the hall to the bar (that is, to the first place outside the bar), for the purpose of taking a principal part in the mootings or exercises of the house; and hence they probably derived the name of *utter* or outer barristers. The other members of the Inn, consisting of students of the law under the degree of utter barristers, took their places nearer to the centre of the hall and farther from the bar, and from this manner of distribution appear to have been called *inner* barristers. The distinction between utter and inner barristers is at the present day wholly abolished, the former being called barristers generally, and the latter falling under the denomination of students.

The degree of utter barrister, though it gave rank and precedence in the Inn of Court, and placed the individual in a class from which advocates were always taken, did not originally communicate any authority to plead in courts of justice. In the old reports of the proceedings of courts, the term is wholly unknown; serjeants and apprentices at law, who are supposed by Dugdale to be the same persons, being the only pleaders or advocates mentioned in the earlier year-books. (Case of the Duchy of Lancaster, 4 Eliz., Plowden's 'Reports,' vol. i. p. 213; 'Chronica Judicialia,' p. 165.) In the time of Stow, however, who wrote in the latter part of Elizabeth's reign, it is clear that utter barristers were entitled to act as advocates, as he expressly says that persons called to that degree are "so enabled to be common councellors, and to practice the law both in their chambers and at the barres." The exact course of legal education pursued at the Inns of Court before the Commonwealth is extremely uncertain, but it appears to have consisted almost entirely of the exercises called *readings* and *mootings*, which have been described by several ancient writers. The *readings* in the superior or larger houses were thus conducted: The benchers annually chose from their own body two readers, whose duty it was to read openly to the society in their public hall, at least twice in the year. On these occasions, which were observed with great solemnity, the reader selected some statute, which he made the subject of formal examination and discussion. He first recited the doubts and questions which had arisen, or which might by possibility arise, upon the several clauses of the statute, and then briefly declared his own judgment upon them. The questions thus stated were then debated by the utter barristers present with the reader, after which the judges and serjeants, several of whom were usually present, pronounced their opinion *seriatim* upon the points which had been raised. Readings of this kind were often published, and it is to this practice of the Inns of Court that we are indebted for some of the most profound juridical arguments in our language, such as Callis's reading on the Statute of Sewers, and Lord Bacon's on the Statute of Uses.

The process of *mooting* in the Inns of Court differed considerably from *reading*, though the general object of both was the same. On these occasions, the reader of the Inn for the time being, with two or more benchers, presided in the open hall. On each side of the bench table were two inner barristers, who declared in law French some kind of action, previously devised by them, and which always contained some nice and doubtful points of law, the one stating the case for the plaintiff, and the other the case for the defendant. The points of law arising in this fictitious case were then argued by two utter barristers, after which the reader and the benchers closed the proceeding by declaring their opinions *seriatim*. These exercises appear to have lost much of their utility in the time of Lord Coke, who, in the 'First Institute,' p. 280 *a*, praises the ancient readings, but says that the modern performances were of no authority. Roger North says that Lord Keeper Guildford was one of the last persons who read in the Temple according to the ancient spirit of the institution. It is, however, beyond all doubt, that, as far back as we have any distinct memorials, all advocates must have passed through the mode of preparation adopted in the Inns of Court.

The serjeants, who, before the allowance of utter barristers to plead in courts, appear to have been the only advocates, were called by writ from the Inns of Court, the writ commanding the person to whom it was addressed to take on himself the dignity of the coif, being only issued at the discretion of the crown, and generally as a matter of favour. This continues to be the case at the present day, although practically the nomination of serjeants is in the hands of the Chief Justice of the Court of Common Pleas. In process of time it became convenient and necessary to enable utter barristers to practise; but some time after they began to act as advocates in the superior courts, the terms upon which they were called to the bar, and allowed to plead, were prescribed by the Privy Council. Thus an order of council regulating the proceedings of all the Inns of Court in this respect, dated Easter Term, 1574, and signed by Sir Nicholas Bacon as lord keeper, and several lords of council, directs that "none be called to the utter bar but by the ordinary council of the house (that is, the Inn), in their general ordinary councils in term time; also, that none shall be utter barristers without having performed a certain number of mootings; also, that none shall be admitted to plead in any of the courts at Westminster, or to sign pleadings, unless he be a reader, bencher, or five years' utter barrister, and continuing that time in exercises of learning; also, that none shall plead before justices of assize unless allowed in the courts of Westminster, or allowed by the justices of assize." (Dugdale's 'Origines Juridiciales.') This appears to be the last instance of the immediate interference of the Privy Council with the arrangements of the Inns of Court respecting calls to the bar. In the reigns of James I. and Charles I., the judges and benchers of the several Inns conjointly made orders on this subject, and, since the Commonwealth, the authority to call persons to the degree of barrister-at-law has been tacitly relinquished to the benchers of the different societies, and is now considered to be delegated to them from the judges of the superior courts. In conformity with this view of the subject, the practice has been, in the several cases of a rejection of applications to be called to the bar which have lately happened, to appeal to the judges, who either confirm or reverse the decision of the benchers. From the history of the system, however, it would appear as if the judges themselves possessed only a delegated authority from the crown.

Previously to a general arrangement made by all the Inns of Court in 1762, the qualifications required for being called to the bar varied extremely, and no uniform rule was observed at the different houses. In the first year of the reign of James I. it was solemnly ordered by a regulation, signed by Sir Edward Coke, Sir Francis Bacon, and other distinguished names, that no person should be admitted into any of the Inns of Court *who was not a gentleman by descent*. Other regulations were occasionally made, as to the length of standing required, and the number of persons to be called at each time, which were often absurd and inconsistent with each other. The greatest inconvenience, however, arose from the absence of uniformity in the practice of the different Inns, as to the qualifications which they respectively required. To remedy this evil, it was determined, in 1762, by the concurrence of all the Inns of Court, to adopt a common set of rules for their guidance in this respect; and under these rules, which were slightly modified by the different Inns of Court from time to time, the only qualifications required, until quite recently, were, that a person should be twenty-one years of age, and have kept twelve terms, by eating the number of dinners *during term* necessary to constitute *keeping* that term. The candidate must thus have been *three years* a member of the society to which he belonged, and during that time he was required to go through certain formalities, called *keeping exercises*, which meant nothing. No knowledge of law was required; but the candidate must have been able to write his name, and either to read writing or to recollect some words of his exercise. By an order made by the benchers of the Inner Temple, in Trinity Term, 1829, every person proposed for admission to that house must, previously to his admission, have undergone an examination by two barristers appointed by the bench, who were required to certify whether the individual was proficient in 'classical attainments and the general subjects of a liberal education.' This regulation was never adopted at any of the other three Inns of Court; it was felt, or supposed to operate, as a restraint upon the resort of students to the Inner Temple, and to create a consequent diminution of its funds. The rule was abandoned in 1847.

In 1852, the four societies agreed upon a new set of rules, by which the previous rules were almost entirely re-enacted. A student is now compelled to attend two of the five courses of lectures delivered at the halls of the Inns of Court, during one whole year; the year being divided for this purpose into three educational terms. He may, however, avoid this attendance by submitting himself to an examination in law. Lectures have been instituted and lecturers appointed, and a body called a 'Council of Legal Education' created. One studentship of fifty guineas per annum, tenable for three years, may be conferred by this council on the student who passes the best examination, at the general examinations, which are held at the beginning of every educational term. As the examination is voluntary, this is the inducement held out to students to offer themselves; besides which, two of the terms of successful students may be dispensed with, and they may thus, and not otherwise, take precedence at the bar of men otherwise of their own standing. Students, it may be added, are now charged an extra five guineas at their admission, one guinea being paid over to each lecturer.

The opinions of the bar are very much divided as to the utility of these lectures and studentships. The *keeping of terms* at an Inn of Court constituted the merely formal part of the preparation for the bar. It was not unusual for a student to pass three years in the chambers of a gentleman in practice, and in this way to obtain an actual knowledge of law, and qualify himself for the actual practice of his intended profession. If three years were not always given to study, a lesser period must have been passed *in statu pupillari*, there being no other mode of acquiring the practical knowledge thus obtained. It is admitted universally that the lectures are not intended or expected to give this practical knowledge of the profession, and it is contended by those who have had the most ample means and opportunity of forming an opinion, that a knowledge of the law is only to be gained by a close, continuous, and uninterrupted study, and that lectures can be of little, if of any use, in directing the student in his course. As yet, no practical good is known to have resulted from the new system, which, however, must still be considered experimental.

The expense of being called to the bar amounts to between 80*l.* and 90*l.*, exclusive of the three years' commons and the admission fees *supra*. In order to qualify a person for the bar in Ireland, it is necessary that he should have kept six terms at one of the four Inns of Court in London, and six terms at the King's Inn in Dublin. After a student has kept the necessary number of terms, he may be admitted to practise *under the bar*, as it is termed. Persons thus practising the common law are termed *special pleaders;* those following a similar course in the courts of Chancery, *equity draftsmen*. They must take out an annual certificate, like attorneys, and are generally paid much smaller fees than barristers; but they can charge their fees and recover them by action, which a barrister is unable to do. Some of these practisers *under the bar*, as well as members of the bar, devote themselves to one branch of practice in chambers, and are thence called *conveyancers*. [COUNSEL; INNS OF COURT.]

BARRISTER. In Scotland, there was (if we except public *Notaries*) till modern times but one order of law practitioners. They had various names,—procurator, advocate, prolocutor, forespeaker: of which the two former were the most frequent, and the first is to this day the judicial style of the advocates of the college of justice, the advocate of the church of Scotland, and the fiscals and practitioners of the local courts. They were at once the chamber-counsel, the barrister, and the attorney of their clients; and, in the common law courts at least, all pleaded *within* the bar. This continued to be the case till the institution of the Court of Session in 1532, when it was enacted "that nane advocat nor procuratour within the bar stand to pley, bot passe outwith with the partie, except the king's advocat:"—an enactment which, being limited to the Court of Session and inferior courts, is unknown in the Court of Justiciary, where to this day, both at Edinburgh, and on the circuit, all plead as of old *within* the bar. We soon afterwards find in the records a new class of law practitioners under the name of *writers*, acting below the bar; but against them the censures of the court were constantly proclaimed, and they were ordered to be *extruded* from the court; and we also find that, by the Secretary of State's injunctions in 1594, the *writers to the signet* were forbidden to act as agents, that is, attorneys or solicitors in court. The *writers*, however, had taught division of labour in the legal profession; and the business of the Court of Session accordingly was soon divided between the advocates and their clerks—all except whom were, by act of Sederunt, 13th July, 1596, prohibited to act as agents, and this order was renewed by statute 1672, c. 16, s. 31, and by act of Sederunt, 26th February, 1678. By a bye-law of the writers to the signet, also, December, 1676, any member of that body who should act as an agent was made liable to be prosecuted. Nevertheless, the writers to the signet came ultimately to act as agents; and in the course of last century, a third class of agents was established under the name of solicitors before the supreme courts. These several classes of agents can act in court only below the bar, whereas the advocates are not confined to the bar, but remain undivested (except by usage) of their ancient right to act both as counsel and attorney.

Thus far as to the Court of Session. In regard to the local courts, the resident practitioners are styled *procurators*, except at Aberdeen, where, agreeably to an act of court passed by Mr. Sheriff Crombie in 1633 (perhaps the first local-court regulation in Scotland subsequently to the establishment of the Court of Session), the practitioners are admitted to practise (as in the Court of Session) as "advocates and procurators," and are usually styled advocates in Aberdeen. These, and the procurators of the other local courts, act, as of old, in every branch of juridical business. They are admitted by the court before which they intend to practise, and cannot act before any other county court.

The advocates of the College of Justice, who form the Bar of Scotland, are not restricted to the Court of Session, but are entitled to act in every court in the kingdom (except where specially excluded by statute), and they go on circuit with the superior criminal court; but no practising member of the bar is permanently resident in any of the provincial towns; and there is not yet, therefore, any *provincial bar* in Scotland, as in England.

The advocates of the College of Justice form an incorporation called the Faculty of Advocates. All matters relating to the body are regulated by the vote of the whole members, and there is no governing council resembling that of the benchers of the English Inns of Court. The president of the body is called the Dean of Faculty, and is elected by general vote. He has precedence in court after the Lord Advocate for the time being, and before the Solicitor-General. No other precedence is recognised, except that of seniority. But by a recent resolution the Faculty has resolved of courtesy to permit those who have held the offices of Lord Advocate and Solicitor-General to have precedence next after the Lord Advocate, Dean of Faculty, and Solicitor-General for the time. But only the actual Lord Advocate and Solicitor-General plead within the bar. The Faculty regulates all matters connected with admission to the bar.

Till the institution of the Court of Session in the beginning of the 16th century, no course or exhibition of legal learning appears to have been required to qualify for the legal profession in Scotland. At first indeed no legal qualification was necessary even for the Scottish bench. The first advocates were mostly, if not all, ecclesiastics, conversant with the canon and civil laws; and, till the Union with England, a knowledge of these laws was the chief requisite to admission to the Scottish bar. Indeed, till the above era, there was no provision for the study of the law in Scotland, except the canon and civil law chairs of the universities; and accordingly it was usual till our own day to prepare for the Scottish bar at some one of the foreign colleges; of which those of France and Italy were the most frequented, till the lustre of the Cujacian school in the Low Countries, aiding the connection which arose between Scotland and them at the Reformation, drew the student thither. In 1722, however, a chair of *Scots Law* was erected at Edinburgh; and there are now several law professorships in the different universities of Scotland.

From the year 1610, it has been imperative on all candidates for admission to the bar in Scotland to pass an examination in law. In the year 1750 it was required that this examination should be both upon the civil law and the law of Scotland. A further extension of the course of study was made in 1854, when an examination, or the production of other evidence of proficiency in several branches of general learning, was directed, prior to the examination in law. These preliminary qualifications are as follows:

The degree of M.A. of any Scottish university, of the University of London, or of the Queen's University in Ireland, or the degree of B.A. of the English universities, or such degree of a foreign university as may be evidence of the same amount of scholarship as the degree of M.A. in Scotland.

In the event of the candidate not having graduated as above, he must undergo an examination on the following subjects and books,—

1. Latin.—'Cicero de Oratore,' and the 'Odes' of Horace, or in place of Horace, the first six books of the 'Æneid.'
2. Greek.—First six books of the 'Iliad,' or Herodotus's 'History.'
   In place of the Greek, the candidate may select any two of the modern languages subjoined:
   German.—Schiller's 'Geschichte des Abfalls des Vereinigten Niederlande, &c.,' and Schiller's 'Historical Dramas.'
   French.—Guizot's 'Histoire de la Civilisation en Europe,' and a Satire of Boileau.
   Italian.—Beccaria, 'Dei Delittie e delle Pene,' and a Tragedy of Alfieri.
   Spanish.—Cervantes, 'Don Quixote,' and Yriarte, 'Fabulas Literarias.'
3. Logic.—Whately's 'Logic.'
   In place of Logic the candidate may select
   Mathematics.—First six books of Euclid.
4. Ethical and Metaphysical Philosophy.—Reid's Works by Hamilton, and Sir J. Mackintosh's 'Dissertation on Progress of Ethical Philosophy.'

A year after passing this examination, the candidate may present himself for examination in law. But for a year prior to the examination in law, he must not have engaged in any trade, business, or profession, either on his own account or in the employment of another. And he must have attended, during at least one session, a class of civil law in a university, and during another session a class of Scots law in a university; and attended during one session a class of conveyancing, or during a second session, either of the classes first mentioned; and lastly, he must have attended a course of lectures on medical jurisprudence.

The examination on civil law is appointed to be on the 'Institutes of Justinian,' with Warnkœnig 'Inst. Jus. Rom. Privat.;' and the title of the Pandects 'De div. reg. juris' (lib. l. tit. vii.) with the Commentary contained in the 45th title of the 4th book of Bankton's 'Institute of the Law of Scotland.' The examination on the Scottish law is appointed to be on Bell's 'Principles.'

If the examination is successfully passed, a title of the Pandects is assigned to the candidate as the subject of a thesis in Latin. Unfortunately it is not required that the thesis should be actually, as it is nominally, of the candidate's own composition, and this is consequently, what no other part of the examination is, a mere formality. When the thesis has been approved, the candidate is presented to the Court of Session, by which he is formally admitted as an advocate. The fees on admission amount to about 350*l.*; the greater part of which goes to the support of the magnificent library belonging to the Faculty.

Among the curious trifles of which the memory is still preserved by antiquaries, is the right claimed by the Scottish bar to remain covered in the presence of the court. Thus we find that Alexander Seton, afterwards Lord Chancellor of Scotland, "made his public lesson of the law before James VI., the Senators of the College of Justice, and Advocates present, in the Chapel Royal of Holyrood House, in his lawyer-gown and four-nooked cap (as lawyers used to pass their tryals in the Universities abroad), to the great applause of the king and all present; after which he was received by the College of Justice as ane lawyer." And so, when King Charles removed Oliphant, King's Advocate, from the bench, and issued an ordinance that no officer of state should for the future have the place of an ordinary lord there, the Court of Session passed an act of Sederunt, acknowledging the right of his assistant and successor, Hope, King's Advocate, to plead covered. This, it is indeed said, was a privilege granted to Hope personally, in consideration of his having a son, or as some say two sons, and others, who not content with *one* or *two*, roundly assert *three* sons on the bench, who like the other judges sat with the hat on. But the fact is, Hope had *no* son on the bench when the act of Sederunt referred to was passed, nor for six years afterwards; and the acknowledgment then made was renewed to Sir Thomas Nicholson, King's Advocate, with other known privileges of the office of King's Advocate. We therefore take the act of Sederunt to contain recognition of a right common to the whole faculty, and made to the King's Advocate as the head of the body under the bench. That the judges wore their hats on the bench till recent times is certain; and at admissions to the bar the hat is to this day placed on the bar of the court in assertion of the right of the candidate. A general parity indeed prevails between the bench and bar: the King's Advocate and others were long members of both bench and bar; and in former times, when the judges were removable at pleasure, if a judge was removed from the bench he resumed his practice at the bar. This, for example, President Balfour did, on his removal from the chair.

BARROW. [TUMULUS.]

BARTER, a rule of Arithmetic, introduced into books which teach rules without principles, but which, though a very necessary and usual application of arithmetic, would be too obvious a consequence to be introduced into any system of demonstrative arithmetic. It means the exchanging of goods against goods, not against money, and, as might be supposed, the rule is the following:—

"Find the value of that commodity whose quantity is given; then find what quantity of the other at the rate proposed you may have for the same money, and it will be the answer required." (Bonnycastle's 'Arithmetic.') Thus, to find how many oranges at 2 a penny should be given for 150 apples at 3 a penny, find how much money 150 apples cost at 3 a penny, namely 50 pence, and find how many oranges can be bought for 50 pence at 2 a penny, namely 100.

BARTER. When one commodity is exchanged directly for another, without the employment of any instrument of exchange which shall determine the value of the merchandise, the transaction is called Barter. All trade resolves itself into an exchange of commodities; but the commercial exchangers of one commodity for another effect their exchanges by a money-payment, determined by a market-value. This is a Sale. Swift, in his attack upon Wood's halfpence, which he considered as destructive of the money-standard of value, says, "I see nothing left us but to *barter* our goods, like the wild Indians, with each other." The general evils of such a state are obvious; and they create dishonest attempts in one exchanger to cheat the other. The North American Indians obtain a few of the comforts and luxuries of civilised life by exchanging skins for manufactured articles. The Indians meet the traders: each man divides his skins into lots, which have a relative value to each other, as that two otter skins are equal to one beaver. For one lot he wants a gun, or a looking-glass, or a blanket, or an axe. The trader has the articles to give the Indian in exchange. Twenty beaver-skins are given for a gun; the gun costs a pound in Birmingham; the beaver-skins are worth more than twenty times the amount in London. If the Indians were brought into more general contact with the exchangers of civilised life, they would regulate their exchanges by a money-standard, and would obtain a fairer value for their skins.

The term *barter* seems to have been derived from the languages of southern Europe: *baratar*, Spanish; *barattáre*, Italian,—which signify to cheat as well as to barter; hence, also, our word Barratry. The want of a standard of value in all transactions of barter gives occasion to that species of overreaching which prevails from an ignorance of the real principles of trade, by which all exchangers are benefited through an exchange. The examples of barter, however, without any reference to some standard of value, become more and more uncommon, as the commercial intercourse of mankind advances. A skin of corn, or a stone vessel of corn, among some of the Indian tribes, is established as a standard of value; councils are held to determine the rate of exchange; and a beaver-skin is thus held to be worth so many more skins of corn than a blanket. This is an approach to a standard of value which almost takes the transaction out of the condition of being a barter. In the trade carried on between Russia and China, the exchanges of merchandise are directly effected, but the comparative value of the merchandise is determined by a money-standard. This is clearly not barter. The Indian corn measure of value is something like the animal measure which formerly existed in this country, when certain values being affixed to cattle and slaves, they became an instrument of exchange, under the name of *living* money. Amongst the northern nations skins used to be a standard of value: the word *rāha*, which signifies money in the Esthonian language, has not lost its primitive signification of skins amongst the Laplanders. When nations come to use any standard of value, whether skins, as in northern Europe, or dhourra (pounded millet, *Sorghum vulgare*), as in Nubia, or shells, as in parts of India, their transactions gradually lose the character of barter. If wages are paid in articles of consumption, as in some mining districts of England, the transaction is called *truck;* —*troc* is the French for barter.

The exchanges of a civilised people amongst themselves, or with other countries, are principally carried on by bills of exchange: the actual money-payment in a country by no means represents the amount of its commercial transactions. If any sudden convulsion arise which interrupts the confidence upon which credit is founded, bills of exchange cease to be negotiable, and exchangers demand money-payments. The coin of a commercial country being insufficient to represent its transactions, barter would be the natural consequence if such a disastrous state of things were to continue. Thus, when Mr. Huskisson declared in 1825 that the panic of that year placed this country "within forty-eight hours of barter," he meant that the credit of the state would have been so reduced, that its notes would not have been received, or its coin, except for its intrinsic value as an article of exchange; and that the bills of individuals would have been in the same case. Barter, in this case, would be a backward movement toward uncivilisation.

BARTHOLOMEW, HOSPITAL OF ST. [HOSPITALS.]

BARYTA, BARYTES. [BARIUM.]

BA'RYTON, or BARITONE, from βαρὺς, heavy, grave, and τονὸς, tone, the male voice, the compass of which is between that of the tenor and the base. Dr. Bennati, in his 'Recherches sur la Mécanisme de la Voix Humaine,' applies a new term, *baritenor*, to this voice, which is much to be preferred to the above, for that, according to its etymological meaning, would seem to imply a low rather than a high base.

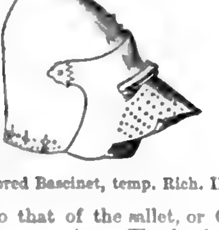
BARYTON is the name of an instrument similar to the viol da Gamba [VIOL DA GAMBA], invented in 1700, but now entirely disused. Haydn composed no less than 163 pieces for the baryton, or *baritono*, which was the favourite instrument of his patron, Prince Nicola Esterhazy.

BASCINET, BASINET, or BASNET, was a light helmet, so called from its resemblance to a basin. It was introduced about the time of Edward I. and replaced the chapet-de-fer, being worn commonly with the nasal, which however disappears after this reign.

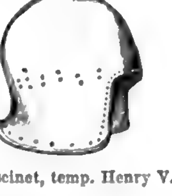
Finchet, says Grose (it should be Fauchet, 'Origines des Chevaliers, Armoiries, et Héraux,' 8vo, Paris, 1606, p. 42 b.), supposes the bascinet to have been a lighter sort of helmet that did not cover the face, and says he finds that the knights often exchanged their helmets for bascinets when much fatigued, and wishing to ease and refresh themselves, at a time when they could not with propriety go unarmed. An example of this kind, copied from a brass in Minster Church, Sheppey, of the time of Edward II. is appended.

Bascinets were worn in the reigns of Edwards II. and III. and Richard II. by most of the English infantry, as may be repeatedly seen in the rolls of Parliament and other public records.

In the reign of Richard II. a novelty in the form of the bascinet was introduced: it was then furnished with a species of moveable visor, a ventaille, bavière, or visière, as it was indifferently called, of which an example, copied from Sir S. Meyrick's 'Engraved Illustrations of Ancient Arms and Armour,' is given below, together with one when it had resumed its simpler form, of the time of Henry V. copied from one in Sir S. Meyrick's collection. The form is



Visored Bascinet, temp. Rich. II.



Bascinet, temp. Henry V.

tending to that of the sallet, or German headpiece, which came into use in the next reign. The knob on the top is intended to hold the panache or plume, which was introduced as a crest in the time of Henry V.

(Grose, *Treatise on Ancient Armour;* Meyrick, *Critical Inquiry into Ancient Armour;* Planché, *History of British Costume.*)

BASE. The name base is applied in chemistry to those elements or groups of elements which combine with halogens or with acids to form, in inorganic chemistry, salts, or, in organic chemistry, bodies analogous to salts.

As it appears that every two elements may combine together, it follows that the basicity of an element is nothing absolute, but wholly relative to the other element or elements present. Thus, in one binary compound an element may be basic to another element, while in another compound the first element may be halogenous to a third. This being the case even with binary compounds, bodies which contain more than two elements show this ambiguity to a greater extent; for in such cases a body which is basic to a second may, when combined with a third, form a compound which is halogenous to a fourth. There are no separate terms for compound bases and simple or elementary ones, corresponding to the terms halogen and acid, employed in distinguishing simple and complex base-combiners.

But although no absolute line of demarcation between basic bodies and acids or halogens exists, yet in compounds resulting from the union of the two, it is generally possible to determine which function is exercised by each of the elements or groups of elements. This can only be done by analogy: by comparing such compounds with others, the functions of whose constituents are assumed as known. Thus, if in hydrochloric acid (HCl) we admit the hydrogen to be basic, then when zinc dissolves in hydrochloric acid, the zinc, in the chloride of zinc formed, must occupy the same position and perform the same function towards the chlorine, as did the hydrogen which it has expelled—that is, it must be basic. Again, on treating nitrate of silver with the so-formed chloride of zinc, the silver displaces the zinc to form chloride of silver, and the zinc the silver to form nitrate of zinc. Hence, the silver of chloride of silver stands in the same relation to the chlorine as that which was maintained by the zinc, and therefore also by the hydrogen; it is therefore basic. Moreover, the formation of nitrate of zinc shows that in this latter body the zinc and nitric acid are related to one another in the same manner as the silver and chlorine in the chloride of silver, the two metals having simply changed places.

By insisting upon the symmetry of the recompositions which occur in analogous interchanges, some chemists have been led to the symbolisations $AgNO_6$ and $ZnNO_6$ (*mutatis mutandis* for other oxygen salts), instead of those usually employed, $AgONO_5$ and $ZnONO_5$. [SALT.]

The electrolysis of compound bodies by a voltaic current furnishes us with a comparison between the unknown functions of the constituents of one compound, and those of another in which such functions are admitted as known. If a piece of zinc and one of copper be immersed in a vessel (1) of hydrochloric acid, the zinc alone decomposes the acid, evolving hydrogen. On attaching by metallic wires the two plates in (1) with two platinum plates immersed in a second vessel (2) of hydrochloric acid, chlorine is liberated at the platinum plate connected with the copper, hydrogen at that connected with the zinc. If now, instead of hydrochloric acid, we place in vessel (2) another compound liquid and find that it is decomposed, it is clear that the constituents which appear at the two platinum plates are related to one another, as are the chlorine and hydrogen of the hydrochloric acid. On the electrolysis of a compound body, therefore, the substance which separates at the plate in connection with the copper is halogenous or acid, that at the plate connected with the zinc, basic. Since now the plate connected with the zinc is the negative, and the one connected with the copper the positive pole, the terms electro-positive and electro-negative may, from the voltaic point of view, be substituted for basic, and halogenous or acid. Since dilute sulphuric acid is the acid most usually employed to be decomposed in the exciting cell, the products of decomposition in the decomposing cell are strictly the analogues of the products of the decomposition of dilute sulphuric acid when placed in the same decomposing cell; these are hydrogen and oxygen. But whatever acid be employed in the exciting cell, the same electrolytical products appear at the two poles in the decomposition cell, when the same substance is decomposed.

The determination by electrolysis of the relative basicity of the elements of a compound, is sometimes complicated by secondary recompositions effected by the re-actions of those separated elements upon the original body decomposed, sometimes wholly frustrated by the resistance to the passage of the current.

If metallic copper be placed in a cold solution of chloride of gold, the whole of the gold may be deposited in the metallic state, and its place be taken by the copper, chloride of copper being formed. If metallic iron be placed in the so-formed chloride of copper, copper is deposited and chloride of iron produced. Hence under these conditions copper is more basic than gold, and iron more basic than copper towards chlorine. When metals are compared in this way with one another in regard to their basicity, almost the same order is found to prevail whatever electro-negative constituent is present, and it is therefore possible to construct a list of the metals arranged according to their basicity. Thus in the following table the most strongly basic metals are placed first, and the basic power gradually diminishes towards the end of the list:

Potassium.	Nickel.	Silver.
Sodium.	Cobalt.	Palladium.
Magnesium.	Aluminium.	Platinum.
Manganese.	Lead.	Rhodium.
Zinc.	Tin.	Iridium.
Cadmium.	Bismuth.	Gold.
Iron.	Copper.	

Such a list, however, does not give the relative basic positions of these elements with infallibility. The physical conditions under which the elements are present, and the nature of the possible compounds which may result, influence their order. Thus, although sodium may decompose the oxide of iron at one temperature, iron decomposes the oxide of sodium at a higher one. For further information on this subject, see CHEMICAL AFFINITY.

Those salts which do not result from the direct combination of a halogen with a metal, but from the union of compounds of the non-metallic elements with metals, are usually supposed to contain the metals in combination with a portion of the non-metallic constituents of the salt. In such cases the group containing the metal is the base. The bases resulting from the union of oxygen with the metals have been most fully examined. Sulphur, selenium, and a few other non-metallic elements, also form bases when combined with metals.

According to the solubility of the metallic oxides in water the metals which they contain are called the metals of the alkalies, of the alkaline earths, and of the heavy metals. The oxides of potassium and sodium are accordingly alkalis; those of barium, strontium, calcium, magnesium, the alkaline earths; while the remaining oxides, those of the heavy metals are almost absolutely insoluble. Metals may be basic when in combination with a certain proportion of oxygen, and acid when combined with a larger quantity. This is the case with iron, manganese, chromium, and others. Sometimes one and the same stage of oxidation of a metal may be basic to an acid, and acid towards a base: such are the oxides of aluminium, zinc, and tin. Antimony and arsenic, which occupy an intermediate position between the metallic and non-metallic elements, combine directly with chlorine as bases, while their oxides form well defined acids.

The same two semi-metals in combination with sulphur play the part of acids, not only to the oxides but to the sulphides of the alkalies, giving rise thereby to the salts of sulphur bases alluded to above. Thus the ter- and penta-sulphides of arsenic and antimony combine with the sulphides of potassium, sodium, and ammonium, giving rise to sulphur salts, of which sulpharseniate of sulphide of potassium may be taken as an example. Gold, platinum, and tin, in combination with sulphur, also act as sulphur acids towards the oxides and sulphides of the alkalis.

A metallic chloride may be regarded as playing the part of a base, as for instance, the potassio-chloride of platinum, $KCl\ Pt\ Cl_2$, in which the chloride of potassium is the base, and the chloride of platinum the acid.

In all cases of double salts, indeed, whether resulting from the union of two binary compounds, or of two oxygen salts, we may consider the one salt as the base, and the other as the acid, as seen in the following formulæ:

$$KCl\ Mg\ Cl;\ KOSO_3\ HOSO_3;\ KOSO_3\ MOSO_3.$$

Different quantities of the same base may combine with the same acid, and form well defined salts. The phosphates furnish the most complete example of this. If the phosphate of soda and ammonia ($2NH_4O$, $Na\ OPO_5$), be heated to redness, all the ammonia is expelled, and monobasic phosphate of soda ($NaO\ PO_5$) is left. If ordinary phosphate of soda ($HO\ 2NaO\ PO_5$) be heated, water is expelled and bibasic phosphate of soda remains. If ordinary phosphate of soda be treated with caustic soda, tribasic phosphate of soda ($3\,NaO$, PO_5) separates out on evaporation. Hence phosphoric acid may combine with soda, or soda with phosphoric acid in these proportions, related to one another by weights, as 1, 2, and 3. Phosphoric acid is on this account called polybasic. Antimonic and arsenic acids have also the power of combining with bases in different proportions. Some other acids combine with two, and others again with one or two proportions of base. Among the oxides of the heavy metals, oxide of lead is pre-eminent in possessing the power of uniting in various quantities with acids to form salts which contain more than one basic molecule for every acid one present. [ACIDS, SALTS.]

The non-metallic group ammonia (NH_3), in combination with water as the oxide of the quasi metal ammonium (NH_4), combines with oxygen acids to form salts, in the same manner as do the oxides of the metals proper. Moreover, not only do the hydrochlorate of ammonia, or chloride of ammonium, iodide of ammonium, sulphide of ammonium, &c., present the strongest analogies to the chlorides, iodides, &c., of the metals proper, but such binary salts of ammonium as combine with salts of the metals either binary or oxygen, exhibit the same analogies; thus:

	Analogous to
NH_4O.	KO.
NH_4ONO_5.	$KONO_5$.
NH_4OSO_3, $MOSO_3$.	$KOSO_3$, $MOSO_3$.
NH_4Cl, $PtCl_2$.	KCl, $PtCl_2$.
etc.	etc.

In those hydrogen salts which are called acids (hydrochloric acid, sulphuric acid, &c.), we have seen that zinc and other metals may take the place of hydrogen, and the like substitution may occur in ammonia itself; bodies being formed having the composition

$$\left.\begin{matrix}M\\H\\H\end{matrix}\right\}N,\ \left.\begin{matrix}M\\M\\H\end{matrix}\right\}N,\ \left.\begin{matrix}M\\M\\M\end{matrix}\right\}N.$$

At present however, the basic nature of such inorganic substitution-ammonias has not been sufficiently studied to be discussed here.

Descriptions of the organic representatives of these substitution products of ammonia, where organic molecules replace one or more atoms of hydrogen, will be found under the heads ORGANIC BASE, AMIDES.

BASE, or BASS, a name sometimes given to the violoncello.

BASE, in *music*, from Βάσις (basis), the base or foundation, the lowest part, whether vocal or instrumental. This word is frequently written *bass*, but the etymology, and more especially the pronunciation, are decidedly in favour of the orthography here adopted, which is sanctioned by Dr. Johnson and other high authorities. "The *base*," says Rousseau, "is the most important of parts—the whole harmony is founded on it: hence it is a maxim with musicians, that when the base is good the harmony is rarely otherwise." M. Subzer adopts this opinion; and we do not differ from two such able writers, without having duly considered the question. But if by the words *most important* is meant that which can least be dispensed with, then both assuredly are in error, for the highest part, or melody, is unquestionably the most essential. It is the theme, the subject, without which the other parts, however numerous, are unintelligible. It being understood that we are not speaking of instrumental accompaniments, such as violin, flute, &c., which, in the score, are frequently above the highest voice part or melody. In composition in two parts, the tyro finds it more difficult to write a correct base than a tolerable melody, but to the sound musician the subject and intermediate parts require more thought than the base.

BASE, FIGURED. [FIGURED BASE.]

BASE, FUNDAMENTAL. [FUNDAMENTAL BASE.]

BASE, GROUND. [GROUND BASE.]

BASE LINE. [GEODESY.]

BASE, THOROUGH. [THOROUGH BASE.]

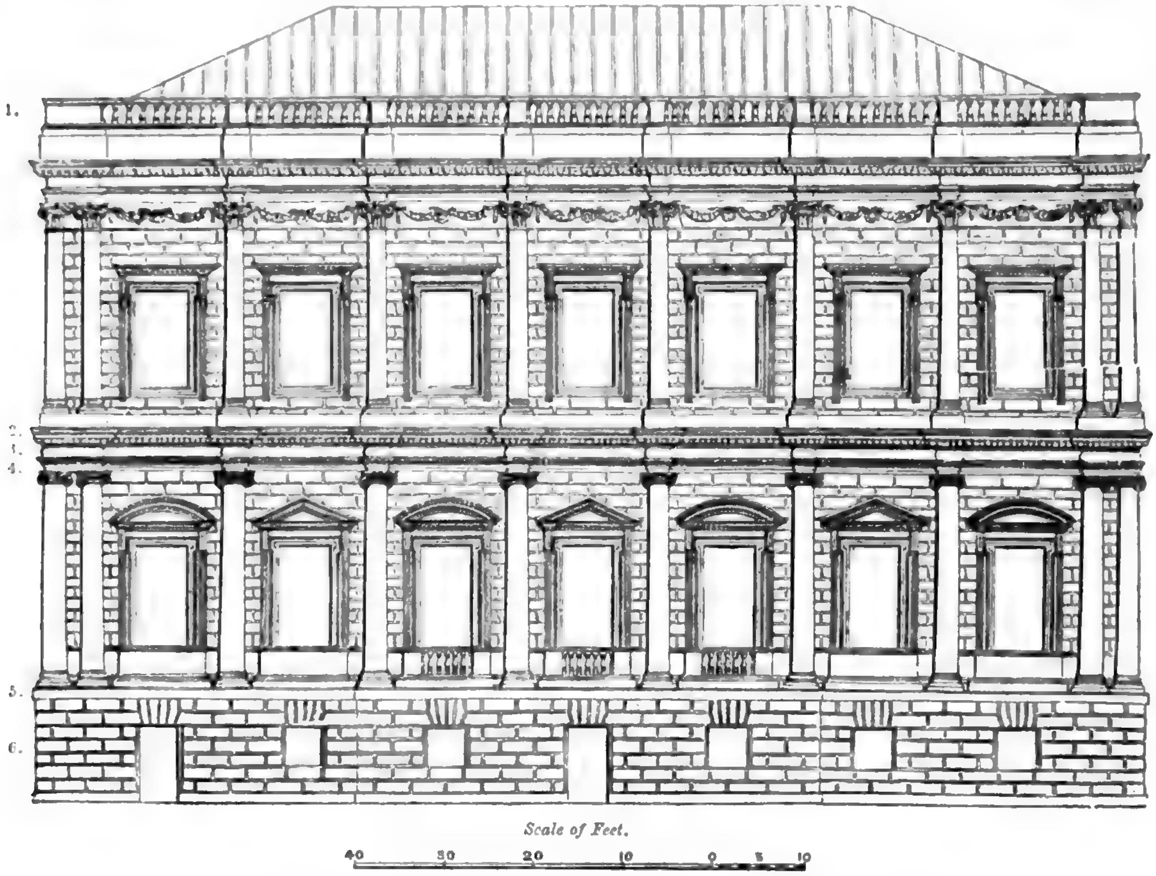
BASE VOICE, the lowest male voice, the usual compass of which is from G or F below the base staff to D or E above it; but some few voices exceed the limits here assigned, and must be considered as exceptions to the rule. Handel, in the aria 'Fra l'ombre,' in his opera of 'Sosarmes,' exacts from the singer a compass of two octaves—from F above the staff to F below; and Purcell, in his anthem 'They that go *down* to the sea in ships,' altogether mistaking the meaning of the word 'down,' and in a wretched endeavour to express descent, writes for the base a run of notes from D above to D below the staff.

BASEL, COUNCIL OF. [COUNCILS.]

BASEMENT, in Architecture, is the lowest story of a building, forming the base of a private house or public edifice. This feature of a building should possess externally the character of strength; and, accordingly, in the designs of Palladio, and the other great masters of the Italian school, we find that the basement has a massive appearance, capable of sustaining the order or orders which are often placed above it. In edifices used as dwellings the basement is high; but in churches and other public buildings it is usually kept low. Some basements are as high in proportion as the floor or story placed above it, while others are not more than a third or a half of the height. The proportions of basements vary according to the conveniences required in the lower story, or to the importance attached to the floor or floors which they may support. Sir William Chambers, in his 'Treatise on Civil Architecture,' gives rules for the proportions of the parts forming the characteristic features of the basement, but at the same time he admits that "the proportions of these basements are not fixed," but depend chiefly on the nature of the apartments forming the ground-floor. "In Italy," he says, "where the summer habitations are very frequently on that floor, the basements are sometimes very high. At the palace of the Porti, in Vicenza, the height is equal to that of the order placed thereon; and at the Thiene, in the same city, its height exceeds two-thirds of that of the order, although it be almost of a sufficient elevation to contain two stories; but at the Villa Capra and at the Loco Arsieri, both near Vicenza, the basement is only half the height of the order, because in both these the ground-floor consists of nothing but offices." These four works enumerated present different proportions, and are all from the designs of Palladio. The true principle is that the proportions of a basement should not be regulated by any rigid rule, but that it be made higher or lower according to the purpose it is intended to subserve in the general design. In the edifices of antiquity the basement is usually low, and intended to support an order of columns. The monuments of Lysicrates and Philopappus at

Athens are, however, examples of high basements. The edifice at Whitehall, to which we have frequently referred, and the Cathedral of St. Paul's, London, have both a low basement.

In basements the masonry is usually rusticated and set upon a plinth, on which there is sometimes a moulded base; the upper part of the basement is surmounted with a broad band, under which, at



Whitehall, London, from a drawing measured and delineated, by Mr. William Barnes, architect.

times, mouldings are employed. A cornice is also used occasionally instead of the band.

In the beautiful palaces of Rome and Florence the basements are finely proportioned. For geometrical representations of these buildings we refer to the architectural work of MM. Percier et Lafontaine, entitled 'Palais de Rome et de Florence.' The published designs of Palladio, Vignola, and Scamozzi, may also be consulted with advantage by the student in architecture.

BASHA. [Pasha.]

BASIL, MONKS OF ST. When St. Basil, bishop of Cæsarea, retired into Pontus, about the year 358, for the convenience of himself and his followers, he founded a monastery, to which he gave a written rule for its regulation, the first of the kind that had appeared, and which was soon adopted in numerous other monasteries. This rule shortly spread itself over the East, and, according to the generality of writers, was not very long in passing to the West. Those who adopted it styled themselves of the order of St. Basil; and St. Basil's Rule was, in fact, the parent of that which was afterwards framed by St. Benedict. (See Schlosser's remarks on Basil, 'Universalhistorische Uebersicht,' &c., 3 th. 3 abth.)

Dom Alphonso Clavel, the Spanish annalist of this order ('Antiguedad de la Relig. y Regl. de S. Basilio,' c. viii. § 2), says that Basil's Rule was approved and confirmed by Pope Liberius in the same year in which it was written and published, A.D. 363; afterwards by several other popes; and was, in a later age of the Church, revised by Pope Gregory XIII., who, about 1573, united the religious of this order in Italy, Spain, and Sicily into one congregation. The abridgment of this Rule made by Cardinal Bessarion, during the pontificate of Eugene IV., and approved by Gregory XIII., was also confirmed by Popes Clement VIII. Paul V. and Alexander VII.

Moréri gives 1057 as the date when the order was introduced in the West. St. Saviour, at Messina, is now considered as its chief monastery in the West. The monks of St. Basil in Spain follow the Greek, those of Italy the Latin ritual. The Greek monks are chiefly of this order, which exists to a great extent in Russia; though in that country, if we may rely on Dr. King, the monks have deviated from their original Rule. He says, "Basil is generally looked upon as the founder of the order of monks which exists in Russia, though, in truth their Rules, at least those they observe at present, are taken from several different persons; as Ephraim of Edessa, Gregory, Chrysostom," &c. (See 'Hist. des Ordres Monastiques,' 4to, Par. 1714, tom. i. pp. 175–238, where engravings will be found of the dresses worn by both monks and nuns of this order in the respective countries; Moréri, 'Dictionnaire Historique,' fol. Par. 1759, tom. ii. p. 154; King, 'Rites and Ceremonies of the Greek Church in Russia,' 4to, Lond. 1772, p. 365; Rodolph, 'Hospiniani de Monach,' lib. iii.)

The order of St. Basil was never, that we know of, introduced into England; though Sir Roger Twysden, in his 'Rise of the Monastic State,' p. 5 (as quoted by Tanner, Pref. to 'Notit. Monast.' p. li.), says, "The monks of Bangor were not unlike the order of Basil, if not of it." The genuine history of the monastery of Bangor, however, in its earliest period, cannot now be traced upon authority which can be relied on.

BASI'LICA (*βασιλικὰ, βασιλικὸς νόμος*). This term denotes a collection or digest of the 'Corpus Juris' of Justinian, translated from the original Latin into the Greek language. This work was commenced and brought to its present state during the latter part of the 9th and the beginning of the 10th centuries, under the superintendence of the Greek emperors of Constantinople. The design of reducing the laws of Justinian into one Greek book from the several Latin collections in which they were known in the Western Empire, is said to have been originally formed, and was certainly in part executed, by Basil I., called the Macedonian, whose reign commenced A.D. 867, and ended in 886, and from whom the book derives its name. Basil's death occurred before the completion of the work; and all that was effected in his time was a kind of Preface, or Introduction, which was called *Πρόχειρον τῶν νόμων*, and consisted of forty heads, or titles. Leo VI., surnamed the Philosopher, who succeeded his father Basil as emperor of Constantinople, brought the collection considerably nearer to its present form. Under his direction it was distributed into six general heads, each of which was subdivided into ten titles; from which circumstance it is entitled in some manuscripts Ἑξάβιβλος (the Six-Book), and in others Ἑξηκοντάβιβλος (the Sixty-Book). The Basilica were however finally reduced into their present form by Constantine VII., commonly called Constantine Porphyrogeneta, the son of Leo the Philosopher, in the early part of the 10th century, and were published under the title ‘Basilica repetitæ prælectionis.’ From that time the book was commonly used as a code of jurisprudence in the Eastern Empire, whilst it still retains its value in our own day, as a treatise explanatory of Justinian's collection of law.

The Basilica contains the code, digests, institutes, and novellæ of the ‘Corpus Juris;’ and in the latter divisions are inserted some of the later edicts of Justinian himself, of the subsequent emperors of Constantinople, and of Basil the Macedonian in particular; and also a few extracts from the fathers, and decrees of early councils of the Church.

The Greek translation of the Roman law was, in all probability, not made expressly for this work, as the four books containing the institutions of Justinian are known to have been in existence in the Greek language previous to the time of Basil the Macedonian.

Hervetus first published, in Latin only, in 1557, four complete books of the Basilica (lib. 45–48), and two books (28, 29) incomplete. A splendid edition of the Basilica, accompanied by a Latin translation and several valuable scholia, and prepared from a collation of various manuscripts in the Vatican and the Bibliothèque du Roi, was published at Paris by Fabrot, in 1647, 7 vols. fol., to which is prefixed a Report to Pope Urban VIII. upon the history of the Basilica, by Joseph Maria Suarez; but this edition only contains thirty-three books complete, and ten others incomplete. Reitz, in 1752, added four books (49–52), following those of Hervetus; but both editions together only contain thirty-six books complete, and seven with considerable lacunæ in them. Cujacius undoubtedly possessed the Greek text of Book 53–59 inclusive; and the manuscript is possibly still extant, or it must have been lost a long time ago. [CUJACIUS, BIOG. DIV.] A new edition has been published since 1835, at Leipzig, by Professor Heimbach of Jena, in which are comprehended the various readings obtained by the collation of several manuscripts not examined by Fabrot. For a history of the Basilica, see Heimbach's treatise ‘De Basilicorum origine fontibus, scholiis, atque nova editione adornandâ;’ see also ‘Thémis ou Bibliothèque du Juris Consulte,’ vols. viii., ix., and x., for some observations upon the use made by Cujacius of the Basilica. Those readers of the Post Justinianean Law who may be prosecuting inquiries into the history and text of the Basilica, will do well to refer to Haubold's ‘Manuale Basilicorum,’ which, in addition to an accurate enumeration of the books and titles, contains abundant references to parallel passages, as well as to the works of modern civilians.

BASI′LICA, from the Greek *βασιλικὴ*, literally signifies a royal residence: but we have no account of any royal residence being specially called by that name; nor have we any description of Greek edifices called Basilicæ, which may be supposed to have furnished the model of the Roman basilica. The name, indeed, is Greek, and it is highly probable that the building itself was framed on a Greek model, though the fact does not appear to be capable of direct proof. The building at Athens, called the Βασίλειος Στοὰ, or Royal Portico, seems to have been pretty much like a Roman Basilica, as to the purposes for which it was used. This edifice, which is mentioned by Demosthenes (‘Against Aristogeiton,’ chap. 6), contained the court of the Archon Basileus [ARCHON]; and the Areopagus occasionally held their sittings there. (See also Pausanias, i. 3.)

The Romans gave the name of Basilicæ to those public buildings with spacious halls, often surrounded with wide porticoes, many of which were built at different times in the various fora of Rome. They were usually called after the person who caused them to be built, as the Basilica Æmiliana, Porcia, &c. (Livy, xxxix. 44.) At the time of the conflagration recorded in Livy (xxvi. 27), B.C. 210, there were no basilicæ then built. We read in the ‘Bellum Alexandrinum’ (cap. 52) that the basilica was used in the Spanish provinces at the date (B.C. 47) to which that work refers.

Copper Coin of Trajan, from the British Museum, representing on the reverse the façade of the Basilica Ulpia.

The principal feature of the Basilica was a large roofed building, supported on columns. The roof, which was called the *testudo*, rose high above the other part of the structure, which consisted of two galleries, called *porticus*, placed one above the other, and round the internal sides of the central building. The porticus was covered with a lean-to roof, the upper part of which commenced below the capitals of the columns which supported the testudo. The light was admitted between the spaces formed by the under line of the architrave of the testudo, the upper line of the lean-to roof, and the perpendicular lines

of the columns. At the end of the central part of the interior a raised platform formed the tribunal for a magistrate. The term testudo, as its name implies, is strictly the roof of the central part; but the term is also extended to signify the whole of the central space, which corresponds to what we call the nave of a church; the porticoes correspond to the aisles.

The basilica was not only used as a hall for the administration of justice, but afforded also convenient shelter to the merchants who transacted business there. Vitruvius, who constructed a basilica at the Julian colony at Fanum, informs us that it ought to be built “on the warmest side of the forum, that those whose affairs called them there might confer together without being incommoded by the weather.” “The breadth,” he says, “is not to be made less than the third, nor more than half, the length, unless the nature of the place opposes the proportion, and obliges the symmetry to be different; but if the basilica has too much length, chalcidica are made at the ends [CHALCIDICUM], as in the basilica of Julia Aquiliana.” (Newton's ‘Translation.’)

The size and proportions of these edifices varied according to circumstances. The following proportions are given by Vitruvius for the various parts of this structure. The columns of the basilica (by which Vitruvius means the columns engaged in the wall) are to be made as high as the porticus is broad; the porticus is to be as wide as the third part of the space in the middle. The columns of the upper gallery must be one-fourth less than the lower. The pluteum (continued pedestal) must be made one-fourth less in height than the upper columns, and be placed between the upper and lower columns, that those who walk above may not be seen by the merchants; from which circumstance it would appear that the upper gallery was intended for a purpose distinct from the uses of the lower gallery. It is probable that in the upper gallery some kinds of handicraft were carried on.

The dimensions of the basilica built by Vitruvius at Fanum were as follow: the testudo 120 Roman feet long, and 60 broad; the porticus between the walls and columns of the testudo, 20 feet broad; the height of the columns of the testudo, including their capitals, 50 feet, and the diameter 5 feet. Behind these were parastaticæ, or small piers, 20 feet high, $2\frac{1}{2}$ feet broad, and $1\frac{1}{2}$ foot thick, to sustain the

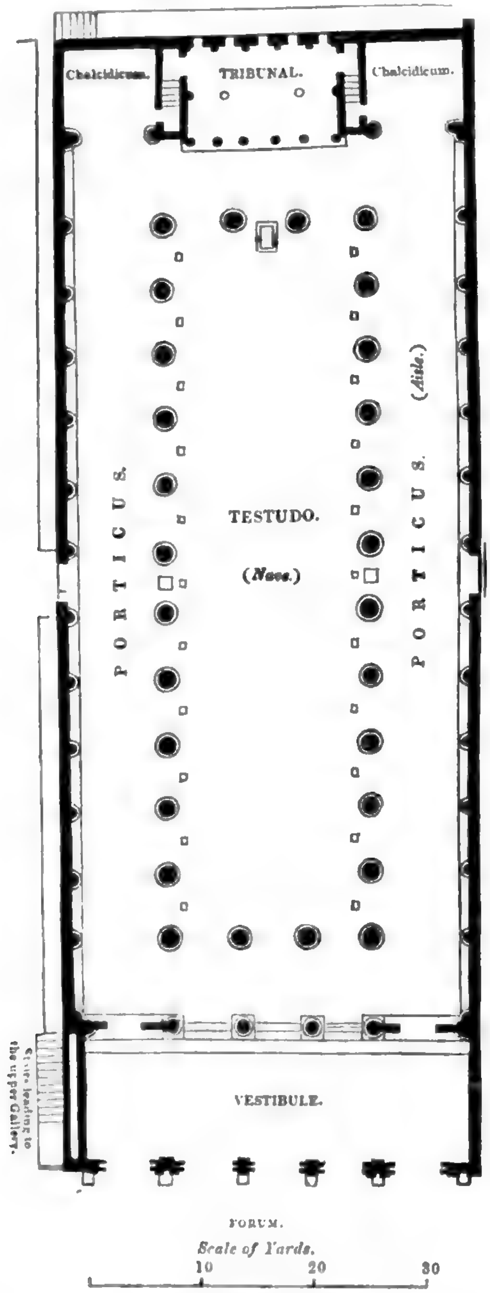
(Drawn according to the dimensions given by Vitruvius.)

beams intended to bear the floor of the gallery. Over these were other parastaticæ, 18 feet high, 2 feet broad, and 1 foot thick, which supported the lean-to roofs. The remaining space between the beams, which were laid over the upper parastaticæ, and the architrave of the columns of the testudo, was open to the light. In the basilica at Fanum, the testudo was supported by eighteen columns, four at each end, six on one side, and four on the other, the two centre columns being omitted on this side, that the view of the pronaos of a temple to Augustus might be seen. The tribunal in this building was in the form of a curved recess, 46 feet wide, and 15 feet deep. To this information Vitruvius adds the proportions of the timbers of the roof.

It is probable that Rome possessed basilicæ in all the different fora of the city. Of these the Basilica of Trajan, which formed a part of the Forum Trajanum [FORUM], is the only one of which there are considerable remains left. Its width was about 180 feet, its length at least double the width. It is represented on the reverse of the medal which we have given above. Another basilica, of the Corinthian order, was discovered on the Palatine Hill. A large edifice in the Forum, called the Temple of Peace, has also been named the basilica of Constantine.

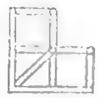
The Emperors Gordian, in their magnificent country residences built on the Via Prænestina, had three basilicæ, 100 feet in length. Two famous basilicæ, Æmilia and Fulvia, were built at Præneste



Plan of the Basilica at Pompeii.

(*Palestrina*), between which Sylla caused a magnificent sun-dial to be placed. The marble fragments of the plan of Rome, now preserved in the Capitol at Rome, which was made during the reign of Septimius Severus, show a part of the Basilica Æmiliana; from which it appears that, unlike the other basilicæ, it had no external wall. In this last respect, it may be compared to a very ancient Greek edifice at Pæstum, which has been generally considered a basilica. This building is an inclosure of columns, without any internal or external walls, and divided in the centre by an order of columns, with another above it. A basilica which was discovered some years since at Otricoli, had a curvilinear recess or hemicycle adorned with statues, which were removed to the museum of the Vatican.

The most perfect basilica of antiquity, and which best corresponds with the building described by Vitruvius, exists in Pompeii, constructed on the south-west, and consequently the warm side of the Forum. This edifice is 220 feet by 80. The testudo rose to the height of about 60 feet, judging from the diameter of the portions of the columns still remaining. These columns are twenty-eight in number, four of which are placed at each end, and the rest on each side of the testudo; they are curiously constructed of brick, and covered with stucco. At the farthest end is the tribunal, raised on a platform, to which the ascent on each side is by a flight of stairs. Under the platform are rooms, conjectured to have been used as temporary prisons for criminals; and in the floor of this platform are circular holes, communicating with the rooms below. On each side of the tribunal are two small square rooms, which, as the Basilica is very long in its proportion, may be considered a part cut off to form Chalcidica. Small engaged columns are attached to the walls inclosing the porticus, on which one end of the beams of the floor were placed, the other being either inserted in the shafts of the brick-columns, or supported on wooden parastaticæ set against their backs, in the manner described by Vitruvius. In the angles the small columns are clustered thus after the manner of Gothic shafts. This arose probably from the circumstance of the beams of the floor of the upper porticus being placed diagonally at the angles, in this manner—



and it is most likely that the under side of the floor was left exposed, as is still the case in the dwellings of Italy, and not covered with lath and plaster, as is the custom in England. The columns being clustered in the angles gave an appearance of strength.

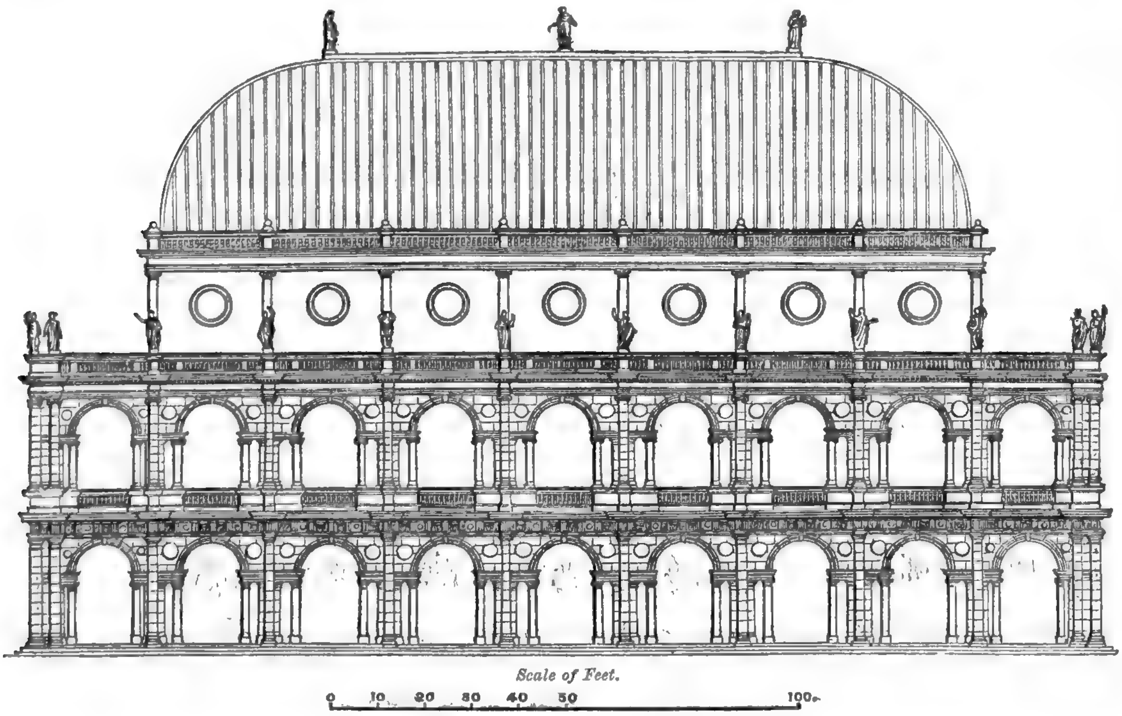
The light, most probably, was admitted in the manner mentioned by Vitruvius; but, in addition, there were windows at the back of the tribunal, which perhaps were at one time glazed, as glass for windows was in common use at Pompeii. The stone door-jambs are remarkable for a large groove, in which we may conjecture that the wooden door-frames were fixed. The doors appear to have folded, as the marks left on the sill from the opening and shutting still remain. The order of the small engaged columns is Corinthian, and the style very similar to that of the Temple of Vesta at Tivoli, and, like that edifice, this Basilica was covered with a fine marble stucco. The most singular decoration is observed in the rusticated plastering of the interior, where the rustics are painted in every variety of colour. The order of the testudo is unknown, as there are no remains of the capitals. It is probable that the columns, from their height, were never covered with the ashes of Vesuvius, which circumstance enabled the inhabitants to remove them.

The early Christian churches of Rome may be considered as the best resemblances of the Roman Basilicæ. In some of them are still found many of the characteristics of the ancient Basilicæ. We give the following list of existing Basilican churches, or parts of churches, at Rome, with their dates (some known, others conjectural), from Bunsen's work on the Basilicæ of Rome, referred to below.—S. Pietro, about 330; S. Paolo, 386; Sta. Sabina, 425; Sta. Maria Maggiore, 432; S. Pietro ad Vincula, 442; S. Lorenzo, 580; Sta. Balbina, 600; St. 'Agnese, 625; Quattro Coronati, 625; S. Giorgio in Velabro, 682; S. Chrisogogno, 730; S. Giovanni a Porta Latina, Sta. Maria in Cosmedin, S. Vicenzo alle Tre Fontane, S. Lorenzo (the nave), SS. Nereo ed Achille,—all about the close of the 8th century; Sta. Prassede, and Sta. Maria in Dominica, in the first quarter of the 9th century; S. Martino ai Monti, 850; Sta. Clemente, 870; S. Nicolo in Carcere, and S. Bartolomeo in Isola, end of 9th century; S. Giovanni in Laterano, 910; Sta. Maria in Trastevere, 1135; Sta. Croce in Gerusalemme, 1144; Sta. Maria in Ara Coeli; Sta. Maria sopra Minerva (noteworthy as a Gothic basilica), 1370; S. Agostino, 1480.

The Marquess Galiani remarks, that the first churches were looked upon as tribunals in which the bishops, &c., administered penance to the guilty and the Eucharist to the absolved. We may therefore observe, in accounting for the resemblance which the early Christian churches bear to the ancient Basilicæ, that nothing could appear at first sight more appropriate than the idea of imitating a tribunal of justice in the construction of the new churches, in which the bishops and priests were to administer a kind of spiritual justice. This remark is well supported by the fact of the bishop's throne being placed in the apsis, or arched recess corresponding to the curved recess or hemicycle, as it was called, of the ancient Basilica. [APSE.] It would seem, in fact, that the obvious convenience of the Basilicæ led the early Christians to convert the ancient Basilicæ into churches, and in their new churches to adopt the principles of that form of building, as these edifices were both light and spacious, and better adapted to the ceremonies of the new religion than the temples of the Pagans.

Constantine has the reputation of having erected the first of these Christian Basilicæ, which was built on the site of his own palace of Lateran, on Mount Cælius. Shortly afterwards he built the Basilica of St. Peter, on the site of the Circus of Nero; and finally commenced a

Interior View of the Basilica of St. 'Agnese at Rome, from a work on Roman Church Basilicæ by I. G. G., Roma, 1823 and 1824.



Elevation of the Basilica at Vicenza, built by Palladio.

third, that of St. Paul, without the walls of Rome. This church was finished fifty years afterwards by Theodosius, who, if we may trust Procopius, built a continuous portico from the city to the Basilica, covered with a copper roof. St. Peter's was decorated with one hundred columns of white marble; it is however now replaced by a more modern structure, the largest of the kind in the world. The external part of the Basilica of S. Giovanni Laterano is of modern construction. St. Paul's without the walls was burnt down some years since, but was afterwards partly restored upon the old plan. The section of this edifice, across the nave, shows the form of the testudo with the inclined roofs of the porticus; and in the spaces between the under side of the roof of the testudo and the upper line of the roof of the porticus, are formed the windows of the church. The other Basilicæ we have not space to notice; but the church of St. 'Agnese exemplifies the peculiar character of the ancient Basilica in so striking a manner, that we give a representation of it, which will illustrate the description of Vitruvius.

In this view will be easily recognised the galleries (porticus) running round three sides of the building, and interrupted by the recess forming the tribunal. In the upper gallery is the pluteum, or continued pedestal, inclosing the same. The nave corresponds to the testudo; the apsis of the church to the hemicycle of the ancient buildings: the only difference is in the manner of piercing the walls for windows, and in the omission of the large columns of the testudo, the two orders of columns standing in the places of the ancient parastaticæ. It is probable that the construction of the roof of the ancient Basilica was exposed, as it is shown here, and as was the invariable practice in almost all the church Basilicæ of Rome. These Basilicæ are built from the old materials of other edifices, and the parts are put together without much regard to symmetry, so that there are often Ionic, Corinthian, and Composite capitals, placed on shafts of columns of various diameters, with portions of entablatures above them, which originally belonged to dissimilar edifices. Santa Maria in Trastevere is an example of these incongruities: here also the throne in the apsis has an antique form, very similar to the hemicycles of the Street of Tombs at Pompeii. The Roman church Basilicæ in their complete form consisted of an atrium, or entrance-court, in the centre of which was the baptismal basin or font; a colonnade, called the narthex, devoted to the use of penitents or catechumen; a nave (*navis*, or *gremium*), where the people assembled to worship; a choir, or chancel, appropriated to the singers and inferior clergy, and in which were the ambones or pulpits; and a sanctuary, or bema, in the centre of which was placed the high altar under a canopy, or baldachin [BALDACHIN], and at the back of which was the apsis [APSIS], in which was the throne of the bishop.

The Roman church Basilicæ are remarkable for their mosaic decorations. [MOSAIC.] The pavements of many of them are enriched with the most elaborate patterns made of the hardest marbles. The arched head of the apsis is often decorated with the figures of saints or apostles upon a gold ground, the whole mosaic being formed of glass tesseræ; but the most sumptuous mosaics are those of St. Peter's, of modern execution, which represent so truly the great works of the best Italian painters, that none but a practised eye can detect the difference.

The general form of the nave, aisles, and apsis of our ancient cathedrals and churches, as well as in those of the Continent, is evidently borrowed from the Italian church Basilica. The nave corresponds to the testudo, and the side aisles to the porticus; the windows of the nave, which externally are seen above the lean-to roof of the aisles, correspond to the opening between the upper part of the columns of the testudo.

Modern Basilicæ exist at the present day in Italy, applied, as the ancient were, to civil purposes. Palladio gives the name of Basilicæ to such public buildings, many of which are found in the Italian towns. Part of the Basilicæ of the present day serve as the palaces of the magistrates, and in them they administer justice, while the lower parts are occupied by merchants, &c. Speaking of these edifices, Palladio says, "Our modern basilicæ differ from the ancient in this, that while theirs were on the ground-floor, ours are elevated on arches, and the parts beneath the arches are used as shops, prisons, and for other public purposes. Another difference is, that the ancient had porticoes only in the interior; the moderns, on the contrary, either have none, or have them on the exterior." There is an example of such a Basilica at Padua, and another at Brescia; but the most celebrated is that at Vicenza, the exterior of which is after the design of Palladio. The body of the building is supposed by Vincenzio Scamozzi to have been erected during the reign and by the command of Theodoric the Goth. This Basilica is 162 feet long by 63 wide; the curved roof is of wood, covered with lead; the great hall is 25 feet 10 inches above the ground-floor, and is supported on piers. This edifice, which reflects great credit on the skill of Palladio, is called at Vicenza "Il Palazzo della Ragione." The architect himself, though a modest man, was so well satisfied with his own performance, that he expressed an opinion that this construction was equal to any Basilica of antiquity.

In England the town-hall, and in France the Palais de Justice, correspond, in some respects, to the modern Italian Basilicæ.

(Vitruvius; Nardini's *Rome*; Nolli's *Plan of Rome, with the Fragments of the Ancient Plan; A Series of Geometrical Plans and Sections, and Perspective Views of the Roman Church Basilicæ*, by I. G. BASKETS. Baskets have been made from the earliest ages, in most countries where pliant willows, reeds, or grasses are to be met with. In England the osier or willow is chiefly used for this purpose; and many of the specimens produced are exceedingly elegant. The willow twigs or other materials are prepared in various ways, according to the costliness of the basket to be made; and the manufacture consists in a kind of interlacing, very simple in its character, and requiring the aid of but few tools. Any of our excellent blind asylums, where industrial pursuits are carried on, will afford a pleasing exemplification of the ease with which basket-making can be carried on by blind persons.

A very large per-centage of the baskets bought by the middle and working classes in London, are made by poor persons, whose wives and children hawk them about the streets for sale. It is precisely one of those trades likely to put on such a commercial aspect—easy to learn, and requiring little or no capital to carry it on.

Foreign baskets are imported to the value of 30,000*l.* to 40,000*l.* annually. Since the period of the Great Exhibition in 1851, Swiss baskets of very light construction, carved in white wood, have become well known in this country.

BASQUE LANGUAGE. This language, Léngua Bascongáda, called also by the Spaniards Bascuence and Vizcaino, and by the French Basque, is spoken by the people who inhabit the Basque provinces, and part of Spanish and French Navarre. The people call themselves Euscaldunac, their country Euscalerria, and their language Euscara, or Escuara. The latter word is derived, according to Larramendi, from *escuco*, free, and *era*, mode or manner. But this is perhaps hardly satisfactory. The elementary syllable in all these words is *Eusc* or *Esc*, which appears in the forms *Vesc* and *Osc* in such names of places as Vesci and Osca, &c.: the true meaning of this element seems doubtful. Balbi, in his 'Atlas Ethnographique,' places the Euscara in the first family of the European languages, and classes it with the Celtic; which opinion, however, few philologists have hitherto adopted. The Jesuit Beovide, quoted by Abate Hervas, says, that having examined the Celtic Dictionary of Leibnitz, he found only two words common to both languages. But upon this we may remark, that the Jesuit must have looked very carelessly not to have found a larger number: if he had carried his inquiries no farther than the numerals to 20 inclusive, he ought to have arrived at a different result. The Basque language is certainly generally supposed to be totally different from all the European languages; an assertion from which entire assent may be reasonably withheld for the present. It is also loosely said to bear some affinity, if not in its roots, at least in its construction, to some of the Asiatic tongues. We may consider the Celtæ and Iberi as two historically distinct nations, without at the same time assuming, what we can never prove, that they do not descend from one common stock. If we are to believe the Basque grammarians, their language existed before the building of the Tower of Babel, and was brought to Spain by Tubal. Setting aside such extravagances, it may be remarked that the testimonies adduced to prove that the Basque language was spoken by all, or nearly all, the primitive inhabitants of the peninsula, are so numerous and conclusive as to amount almost to a demonstration. The etymology of the words denoting the ancient names of mountains, rivers, and towns in almost every part of the peninsula, is one of the strongest proofs. The word España is purely Basque, according to Astarloa, and means lip or extremity: W. Humboldt, however, disputes this explanation, and apparently with good reason. The river Ebro may be derived from *ibai-ero*, a foamy river, or from *urbero*, a warm river; Carpetania is derived from *gara-be*, with the Latin termination *tania*, and means the place at the foot of the hills. The examples of words in which the first element appears to be Basque are perhaps the most striking: such is *acha, aitza*, a rock, which in names of places assumes the form *asta*. Modern names which contain the element are, Asteguieta, Astobeza, Astorga, &c. In Spanish names mentioned by Roman writers the element *asta* also occurs, as in Asta, Astigi, Asta-pa (a dwelling at the foot of a rock), Astures, Asturica, and the river Ast-ura (rock-water). (See Humboldt's 'Inquiries respecting the first Inhabitants of Spain,' p. 23.) The word *briga*, which occurs at the termination of some ancient Spanish names of places, but which appears much more frequently in Gaul, is considered by Humboldt not to be a Basque word. The explanation of this word by Astarloa may serve to show how cautious we should be in following those who have written on this language. *Bri, vri* and *uri*, he says, mean a peopled place; the termination *ga* is negative, so that *briga* means a place without inhabitants, or a place without a town, or a wild population: hence the words *bergante* in Spanish, and *brigand* in French; but as *briga* is always the termination of the name of a town or inhabited place, we must suppose that the word *briga*, in course of time, got a meaning exactly contrary to its primary meaning. Such an hypothesis, as Humboldt remarks, scarcely needs confutation.

All the radicals in the language are significative, even the names of the letters of the alphabet. The Basques write as they speak, and the sound of their letters, whether vowels or consonants, is fixed. It is said that aspirated and guttural sounds did not exist originally in the language. Even at the present day the Basque people give to the *z* a much softer sound than the rest of the Spaniards. According to d'Iharce Bidassouet, quoted by Balbi, the names of the alphabetical characters, nouns, pronouns, and adverbs, may be converted into verbs. The Basque language possesses a great variety of terminations.

Besides terminations equivalent to all those existing in English, it has frequentative, diminutive, and argumentative terminations, like the Spanish and Italian. Verbal nouns are formed with the termination *ari* or *arija*, to denote a physical actor, and *lia*, to denote a moral one: as *gudarija*, a warrior, *iracuslia*, a teacher or doctor. For the abstract substantives it has likewise two terminations, *tassuna* and *querija;* the former denotes a natural and the latter a moral quality, defect, or perfection. Thus, *zoratassuna* denotes madness, as a physical derangement of the mind; *zoraquerija*, an inclination to madness from a strong passion. The possessive terminations are three, *cua*, to denote something contained in the thing expressed by the word; *arena*, to denote the possessor; and *ez* or *ezco*, to express the matter of which it is formed: as *echecua*, contained in or belonging to the house; *guizonarena*, of the man; *olezcua*, made of wood. From the last the Castilians have formed their patronymic, and perhaps their abstract nouns; as *Fernandez*, Ferdinandson; *amarillez*, paleness. The Basque substantives have no sign to express the relation of gender. There is but one article, which is *a* for the singular, and *ac* for the plural. This sign forms the characteristic of nouns as to number, and is in all cases affixed to the substantive: as, *guizona*, *man-the;* *guizonac*, *men-the*.

According to Astarloa, there are but six cases in the declension of the Basque words; but Bidassouet marks eleven. As the preposition is always affixed to the noun, there may be said to exist as many cases as there are prepositions. The verbs are divided into simple, or those expressing a single action, as *icassi*, to learn by one's self; double, as *i-ra-cassi*, to learn by the assistance of another; simple active, as *iltendot*, to kill; and active transitive, as *iltendeutzat*, to kill another. The moods are eleven, and the tenses, according to some Basque grammarians, amount to forty-six. Every verb can be conjugated in twenty-six forms, showing the different relations of the agent to the action and to the object which it affects.

The relation of the speaker to the person spoken to is also expressed by particular terminations. These relations are with regard to sex and dignity. Thus there are five different terminations; namely, masculine and feminine, from an inferior to a superior, and *vice versâ*, and also between equals.

The syntax is very simple, and subject to fixed rules. In every sentence the substantive is placed first, next the article, then the adjective, next the adverb, followed by the verb, and lastly the object, with the preposition affixed to it. Example: *Seme oquer bat-ec emon-d-eus-cuz ardura-one ec;* the literal meaning—"son-crooked-one, given-us-has-to, cares-these;" which means, a bad son has caused these troubles to us. This order is that in which, generally speaking, an illiterate Basque places the words when he attempts to speak Spanish, for which reason the Spaniards call *concordancia Vizcaina* a bad construction.

The Basque is divided into three dialects, not much differing from one another; namely, the Guipuzcoan, the Vizcaino, and the Labortan. The first is the purest, and is spoken in Guipuzcoa; the second, in Vizcaya and Alava; and the Labortan in the French and Spanish Navarre. The only Basque books are grammars and dictionaries, the Bible, books of devotion, proverbs, and songs. In 1824, a very interesting work appeared at Donostian (San Sebastian), upon the ancient usages, dances, games, and songs (of which many still exist, most of them possessing a slow and monotonous character, but with considerable power) of the Guipuzcoans, published by Iztueta, the title of which is 'Guipuzcoaco dantza, gogoangarrien, condaira, edo istoria beren,' &c. The same author published, in 1826, another work, entitled 'The very Ancient Melodies of Viscaya,' &c. This work contains thirty-six airs to as many dances, with their respective words. M. Duhalde, a learned philologist of the Basque nation, has published a work in which he has compared and contrasted the variations found in the different literary productions of the Basque provinces. Le Compte Garat also published, in 1835, 'Fragments inédit. de Littérature Basque,' collected by him.

The best grammars are those of Lécluse in French, and Larramendi in Spanish. The latter author published also a dictionary in Spanish, Latin, and Basque, which is considered the best. Whoever wishes to investigate the very curious structure of the Basque language will derive great assistance from the labours of Lécluse, professor of Greek and Hebrew literature at Toulouse, who published a short dissertation upon the language in 1826, and also his grammar in the same year. Lécluse, in 1828, put forth a proposal for publishing a dictionary of the Basque, Spanish, and French, which it is much to be regretted did not meet with the encouragement which such a work merited.

The following are among the recent works on the Basque language which may be serviceable to the student: the new editions of Larramendi's Dictionary (2 vols. fol., San Sebastian, 1853-4), and Grammar (8vo, San Seb., 1853); S. H. Blanc's 'Grammaire de la Langue Basque, d'apres celle du P. M. de Larramendi,' 8vo, Lyon, 1854; J. B. Archer's 'Grammaire Basque-Française, à l'usage du Pays-Basques,' 12mo, Bayonne, 1854; A. Oihenart's 'Proverbes Basques, suivies des Poésiès Basques,' 2nd ed., Bord., 1847; and the 'Histories of the Early Usages, Language, &c., of the Basque People' (founded on the work of Iztueta), by Chaho (Bayonne, 1850) and Baudrimont, 8vo, Paris, 1854.

BASSET-HORN, a musical instrument, which, notwithstanding its name, is a clarinet [CLARINET] of enlarged dimensions and extended scale, said to have been invented in Germany in 1770, but known to have been produced in an improved state twelve years later by M. Lotz of Presburg; and subsequently, in its present perfect condition, by the brothers, Anthony and John Stadler, of the imperial Austrian chapel. The basset-horn is longer than the clarinet, and the bell end is wider. On account of its length, the tube, which consists of five pieces, is bent inwards, forming a very obtuse angle. The scale of this instrument embraces nearly four octaves,—from C the second space in the base, to G in altissimo, including every semitone; but its real notes, in relation to its use in the orchestra, are from F below the base staff,  to C, the second leger line above the treble, 

The basset-horn takes an intermediate place between the clarinet and bassoon, and, on account of its vast compass, may perform the functions of both. Its capabilities and beauty are strikingly displayed in Mozart's 'Requiem'; and in the aria, 'Non più di fiore,' in his 'Clemenza di Tito'; as well as in other works of the same great composer, who well understood its value.

The Italian name for this instrument, and that by which it is generally designated in scores, is *corno bassetto*, or *rather low horn*, the termination *etto* being a diminutive. The unfitness of this term must at once be obvious: but, unhappily, musical nomenclature abounds in obscurities and contradictions.

BASSIC ACID. [STEARIC ACID.]

BASSO DI CA'MERA, a double-base, or *contrabasso*, reduced in size and power, but not in compass, and thus adapted to small or private rooms.

The dimensions of the body of this instrument are as follows:—

Length	3	feet.
Width above	16	inches.
Width below	21	„
Depth under the bridge	7½	„
Length of strings from bridge to nut	31	„

It has four strings; two of gut and two covered with silver wire, all proportionably thicker than those of the violoncello, and tuned in 5ths, to the same literal notes as the violin, but two octaves lower than the latter. Example:

Hence, and by referring to the article DOUBLE-BASE, it will be seen that this new instrument has a great advantage, in respect to compass, over the other; and in quality of tone it is far superior in chamber music, though neither powerful enough nor designed to supersede, or even to be used as a substitute for, the double-base in the full orchestra.

BASSO-RILIEVO. [ALTO-RILIEVO.]

BASSOON, a musical instrument of the pneumatic kind, blown through a reed. It consists of four pieces, or tubes of wood, bound together, and pierced for ventages, of a brass craned neck, in which the reed is inserted, and of several keys. The whole length of the tubes is 6½ feet, but by doubling up, this is reduced to four. It may be considered as a bass oboe [OBOE]; and its compass is from B flat below the base staff,  to B flat in the treble staff. 

This instrument is used in every kind of music, the richness of its tone and the extent of its scale rendering it invaluable to the composer. Handel seems to have been the first who gave importance to it, and in the air 'Thou didst blow,' in the oratorio of 'Israel in Egypt,' exhibited its qualities in so advantageous a manner, that it immediately afterwards began to assume a rank in the orchestra which it has ever since retained.

The bassoon was invented as early as the year 1539, three years after Luscinius had published his 'Musurgia,' who consequently does not mention the instrument. Mersenne describes it and all its varieties; but a long time elapsed before it came into use. The word is derived from the Italian *bassone*, which is now rarely used. The common Italian term is *fagotto*, a fagot, or bundle of sticks, because the tubes of which the instrument is composed are bound together. The Italian word *fagotto* is always employed in musical scores.

The brass bassoon, with a new system of holes and keys, which excited some attention at the time of the Great Exhibition of 1851, as the invention of M. Sax, was claimed by Mr. Cornelius Ward of London, who had previously taken out a patent for it in France.

BASSOON, DOUBLE, a bassoon of increased dimensions, the scale of which is an octave below that of the ordinary bassoon. The double-bassoon was introduced at the commemoration of Handel in 1784, but not having been found to answer the intended purpose, it fell into disuse, the serpent [SERPENT] well supplying its place.

BASSORIN. [GUM.]

BASTARD. The conjectures of etymologists on the origin of this word are various and unsatisfactory. Its root has been sought in several languages—the Greek, Saxon, German, Welsh, Icelandic, and Persian. For the grounds on which the pretensions of all these languages are respectively supported, we refer the curious to the glossaries of Ducange and Spelman, the more recent one of Boucher, and to the notes on the title 'Bastard' in Bacon's 'Abridgment.'

Among English writers it is applied to a child not born in lawful wedlock, and as such he is technically distinguished from a *mulier* (*filius mulicratus*), who is the legitimate offspring of a *mulier* or married woman.

Our ancestors very early adopted strict notions on the subject of legitimacy; and when the prelates of the 13th century were desirous of establishing in this country the rule of the canon law, by which children born bastards are legitimated upon the subsequent intermarriage of their parents, the barons assembled at Merton (1235) replied by the celebrated declaration, "that they would not consent to change the laws of England hitherto used and approved."

It has been observed, that this sturdy repugnance to innovation was the more disinterested, inasmuch as the lax morality of those days must probably have made the proposition not altogether unpalatable to many to whom it was addressed. The opposition therefore seems to have been prompted by a jealousy of ecclesiastical influence, which was at that time ever watchful to extend the authority of the church by engrafting on our jurisprudence the principles of the canon law.

On another point our ancestors were less reasonable; for it was very early received for law, not only that the fact of birth after marriage was essential to legitimacy, but that it was conclusive of it. Hence it was long a maxim that nothing but physical or natural impossibility, such as the continued absence of the husband beyond seas, &c., could prevent the child so born from being held legitimate, or justify an inquiry into the real paternity.

Their liberality in the case of posthumous children was also remarkable; for in the case of the Countess of Gloucester, in the reign of Edward II., a child born one year and seven months after the death of the duke was pronounced legitimate; a degree of indulgence only exceeded by the complaisance of Mr. Sergeant Rolfe, in the reign of Henry VI., who was of opinion that a widow might give birth to a child at the distance of seven years after her husband's decease without wrong to her reputation. (Coke upon Littleton, 123, b. note by Mr. Hargrave; Rolle's 'Abridgment'—Bastard; Le Marchant's 'Preface to the case of the Banbury Peerage.')

The law now stands on a more reasonable footing, and the fact of birth during marriage, or within a competent time after the husband's death, is now held to be only a strong presumption of legitimacy, capable of being repelled by satisfactory evidence to the contrary.

Another curious position of doubtful authority is also found in our old text writers; namely, that where a widow marries again so soon after her husband's decease that a child born afterwards may reasonably be supposed to be the child of either husband, then the child, upon attaining to years of discretion, shall be at liberty to choose which of the two shall be accounted his father. It was to obviate this embarrassing state of things, that the civil law prescribed an '*annum luctûs*,' or year of grief, during which the widow was prohibited from contracting a second marriage; and our own law provided the now obsolete proceeding on a writ *de ventre inspiciendo*.

The legal incapacities under which an illegitimate child labours by the law of England are few, and are chiefly confined to the cases of inheritance and succession. He is regarded for most purposes as the son of nobody, and is therefore heir-at-law to none of his reputed ancestors. He is entitled to no distributive share of the personal property of his parents, if they die intestate; and even under a will he can only take where he is distinctly pointed out in it as an object of the testator's bounty, and not under the general description of 'son,' 'daughter,' or 'child,' by which legitimate children alone are presumed to be designated. He may however acquire property himself, and thus become the founder of a fresh inheritance, though none of his lineal descendants can claim through him the property of his reputed relations. If he dies without wife, issue, or will, his lands and goods escheat to the crown, or lord of the fee. In the former event, it is usual for the crown to resign its claim to the greater part of the property on the petition of some of his nearest *quasi* kindred.

Strictly speaking, a bastard has no surname until he has acquired one by reputation, and in the meantime he is properly called by that of his mother.

The first English statute which provides for the maintenance of illegitimate children is the 18th of Elizabeth, cap. 3, which confers on justices of the peace the power of punishing the parents, and of requiring from one or both of them a weekly or other payment for their support. Under this and later Acts of Parliament, the usual practice was for the mother to apply for relief to the parish officers, by whom she was carried before certain magistrates to be interrogated respecting the paternity of the child. An order of filiation was then made, and the male adjudged to be the reputed father, and ordered to contribute a weekly payment, or to indemnify the parish against the future expenses of maintenance. (Blackst. 'Com.,' Mr. Kerr's ed., vol. i. p. 480, *et seq.*)

The commissioners appointed in 1832 to inquire into the administration of the Poor-Laws, recommended the exemption of the reputed father from all liability to the support of the child. The proposal was supported by arguments not devoid of plausibility, and is said to be sanctioned by the favourable experience of other countries; it was however strenuously opposed in both Houses of Parliament, and was eventually so modified as to leave the law nearly as it stood before. ('Report of the Commissioners,' pp. 165, 343, 8vo. ed.; stat. 4 & 5 Will. IV. c. 76; 2 & 3 Vict. c. 85.)

The proceedings to affiliate a child are now, except in certain cases, exclusively at the instance of the mother (7 & 8 Vict. c. 101; 8 Vict. c. 10), who is bound in any case to maintain the child, and in case of neglect to do so, may be punished as a rogue and a vagabond. (5 Geo. IV. c. 83.)

The civilians and canonists distinguish illegitimate children into four or five classes not recognised in the English law; it may however be worth while to remark, that the familiar term *natural*, applied by us to all children born out of wedlock, is in that classification confined to those only who are the offspring of unmarried parents living in concubinage, and who labour under no legal impediment to intermarriage. Children of the last-mentioned class are, by the civil and canon law, capable of legitimation by the subsequent union of the parents, or by other acts which it is needless here to particularise. (Heineccius, 'Syntag.' v. i., p. 159; Ridley's 'View,' &c., p. 350, ed. 1675; Godolphin's 'Repertorium Canonicum,' cap. 35.)

By the Athenian law (passed in the archonship of Eucleides, B.C. 403), as quoted by Demosthenes ('Against Macartatus,' cap. 12), illegitimate children were cut out from all inheritance and succession; nor could a man who had legitimate male offspring leave his property to other persons, and consequently not to his illegitimate children. A previous law of Pericles ('Life' by Plutarch, cap. 37) declared that those only were legitimate and Athenian citizens who were born of two Athenian parents. This law, which was repealed or violated in favour of a son of Pericles, was re-enacted in the archonship of Eucleides. (Athenæus, xiii. 577; Demosthenes 'Against Eubulides,' cap. 10.)

The repute in which spurious children have been held has varied in different ages and countries. In some they have been subjected to a degree of opprobrium which was inconsistent with justice; in others, the distinction between base and legitimate birth appears to have been but faintly recognised, and the child of unlicensed love has avowed his origin with an indifference which argued neither a sense of shame nor a feeling of inferiority. When the Conqueror commenced his missive to the Earl of Bretagne by the words, "I, William, surnamed the Bastard," he can have felt no desire to conceal the obliquity of his descent, and little fear that his title would be defeated by it. Accordingly, history presents us with many instances in which the succession not only to property, but to kingdoms, has been successfully claimed by the spurious issue of the ancestor. It is however very improbable that, in any state of society where the institution of marriage has prevailed, children born in concubinage and in lawful wedlock should ever have been regarded by the law with exactly equal favour. (Ducange, 'Glossary,' tit. 'Bastardus.')

Those who may be curious to learn what fanciful writers have urged in proof of the superior mental and physical endowments of illegitimate issue, may refer to Burton's 'Anatomy of Melancholy,' vol. ii. p. 16 (ed. 1821); Pasquier 'Recherches,' chap. 'De quelques memorables bâtards;' and Pontus Heuterus 'de Liberâ Hominis Nativitate.' See also Shakspere's 'King Lear,' act. 1, scene 2; and the observations of Dr. Elliotson in his edition of Blumenbach's 'Physiology,' in notes to chap. 40.

BASTARDY. Under the act of Elizabeth and later acts of parliament, down to the passing of the Poor Law Amendment Act in 1834, the usual practice was for the mother to apply for relief to the parish officers, by whom she was carried before the magistrates in petty session to be interrogated respecting the paternity of the child. An order of affiliation was then made, and the reputed father was ordered to contribute a weekly payment, or was bound to indemnify the parish against the future expenses of maintenance. "In form, the proceeding was against the putative father for the indemnification of the parish; but in substance it was a proceeding of the mother against the putative father, the benefit of which accrued to her, and to which the parish was little more than a nominal party, except when it made good the father's default. It was in truth an action of the mother against the putative father, for a contribution towards the expenses of their common child, in which by a fiction of law, the parish was plaintiff." ('On the law concerning the maintenance of bastards, by the Poor Law Commissioners,' Parl. paper, No. 31, session 1834.) In this state of things the Commissioners of Poor Law Inquiry (1834) recommended that the mother of a bastard should be rendered liable for its maintenance, but that she should be exempted from the punishment under 30th Geo. III. c. 51, and that all enactments charging the putative father should be repealed. The Bill for amending the Poor Law, brought in in 1834, as it ultimately passed (4 & 5 Will. IV. c. 76, ss. 72–76), enacted that the parish might still apply for an order upon the putative father, but this was to be done at the quarter sessions instead of the petty sessions; and corroborative evidence was required; and other difficulties and onerous conditions were thrown in the way, which showed that "the object of the legislature was to impede rather than encourage the applications to quarter sessions." The number of bastards affiliated in England and Wales, in the years ending respectively 25th of March, 1835 and 1836, was 12,381 and 9686. The practice of affiliation was therefore rapidly diminishing under the Poor Law Amendment Act, but it was alleged that the putative father was not punished, while the consequences fell solely upon the woman. In 1839, therefore, an act was passed (2 & 3 Vict. c. 85) which transferred the power of making orders in bastardy from the quarter sessions to any two justices in petty sessions, and facilitated instead of discouraged affiliations. Payments by putative fathers under orders in bastardy, were, under 2 & 3 Vict. c. 85, "limited to the cost of the relief actually given; they have been made bonâ fide to the parish, and therefore the parish has not been a purely formal party to the proceeding, and a mere screen to the woman." (Report of Poor Law Commissioners, Jan. 31st, 1844.) The law respecting bastardy has been still more recently the subject of legislation, and by 7 & 8 Vict. c. 101, the principle of charging the putative father is totally different from that of any previous law on the subject. "Formerly the remedy was intended exclusively for the parish: now the mother alone can obtain it. . . . . . Formerly the chargeability of the child, either in fact or in prospect, was the ground of the remedy: now the actual or probable chargeability of the child is made wholly immaterial." ('Official Circular,' No. 39, Oct. 1, 1844.) The officers of all parishes and unions are deprived of the power of applying for orders of affiliation with regard to illegitimate children, and the mother alone is entitled to apply, at the petty sessions, for such order; but in case of the death or incapacity of the mother, the guardians of unions, or if there are no guardians the overseers, may enforce an order although they cannot apply for one, and payments are to be made to some person appointed by the justices to have the custody of the child, and not to the parish officers; and such person is to receive the child on the condition that it is not to be chargeable. Parish officers are guilty of misdemeanour for endeavouring to promote the marriage of a mother of a bastard, by threats or promises respecting any application to be made for maintenance. The mother of a bastard may summon the putative father before the petty sessions within twelve months after the birth of the child, for the purpose of affiliation, or at any time on proof of money having been paid to her in respect of such child. The justices may then make an order on the putative father for maintenance of the child and other costs, and enforce the same by distress and commitment; but not more than thirteen weeks' arrears can be claimed. The sum paid for maintenance is to be paid to the mother, and if she neglect or desert her offspring she may be punished under the Vagrant Act (5 Geo. IV. c. 83). While unmarried or a widow, the mother is liable for the maintenance of the child until it is sixteen. Any person having the care of a bastard child under an order of maintenance, who maltreats it, or misapplies moneys paid by the putative father for its support, is liable to a penalty of 10*l.* on conviction before two justices. The putative father may appeal to the quarter sessions, as under the old law. The stat. 8 & 9 Vict. c. 10, contains forms, and regulates the proceedings at petty sessions and on appeal. All orders for the maintenance of a bastard cease after it has attained the age of thirteen, or on the marriage of the mother.

In the Savings Bank Act (7 & 8 Vict. c. 83) there is a clause under which the deposits of illegitimate persons who die intestate may be paid to their heirs, as if they had been legitimate; but in other respects the law relating to the succession and inheritance of bastards remains the same. By 6 Will. IV. c. 22, the incapacity of bastards in England to dispose of their moveable estates by will was removed.

The late Mr. Rickman was the first who attempted to ascertain the number of illegitimate births in England. During the progress of the census of 1831, he obtained from the ministers of churches and chapels the number of bastards born in their parishes or chapelries in 1830. The number returned was 20,039. Under the Registration Act (6 & 7 Will. IV. c. 86) no specific reference is made to illegitimate children, but the penalty for making a false statement combined with the local knowledge of the registrars, in most cases prevents such children being registered as born in wedlock. Still there is no doubt that the registrar's returns will give something less than the real number of illegitimate children born. Of the births which escape the vigilance of the registrars, it is most probable that the proportion of those which are illegitimate is greater than in the total registered births. Still-born children are not registered in England, and here again the proportion is higher for illegitimate births than for births in wedlock. In Saxony the proportion of still-born children to 10,000 illegitimate births is 616, in 10,000 other births 464. Whatever may be the number of illegitimate births as they appear on the face of the register, it may safely be assumed that they are below the actual number. If the mortality of illegitimate children were the same as that of children born in wedlock, the number of illegitimate persons living would exceed one million for England and Wales. It is both a social and political evil when so large a proportion of persons exist in any society with ties of a different nature from those of the majority of the population. The condition of an illegitimate child is very frequently a hard one from the moment of its birth.

BASTARDY. The Scottish law of bastardy differs considerably from the English, chiefly in consequence of its having adopted much of the Roman and pontifical doctrines of marriage and legitimacy.

Thus, in England, in the case of a sentence of nullity of a marriage, the issue born during the cohabitation are bastards. But agreeably to the judgment of the canons, 'Decret. Greg.,' lib. iv. tit. 17, c. 14, the Scottish writers, having regard to the *bona fides* of the parties, incline to a different opinion, *in favorem prolis;* and it will be recollected that when Secretary Lethington proposed to Mary Queen of Scots a divorce from Darnley, James Earl of Bothwell, to quiet her fears for her son, "allegit the exampill of himself, that he ceissit not to succeid to his father's heritage, without any difficultie, albeit thair was divorce betwixt him and his mother." The point has not, however, received a judicial determination, and cannot therefore be regarded as settled, though of the tendency of the law there can be little doubt. Even in the case of a marriage where one of the parties is, unknown to the other, already married to another person, still in life, the weight of authority inclines strongly to the side of the legitimacy of the offspring, in favour of the *bona fides* of one of the parents. Of course, the issue of every legal marriage is lawful, and therefore the children not only of marriages regularly solemnised, but also of every union acknowledged by the law as a marriage, are alike legitimate. The same may be said of children legitimated by the subsequent intermarriage of their parents; but the situation of these is, as we shall immediately see, somewhat anomalous.

The Scottish law has adopted two species of legitimation, which, in the language of the civil law, it calls legitimation *per subsequens matrimonium*, and legitimation *per rescriptum principis.*

The former of these was introduced into the Roman jurisprudence by a constitution of the Emperor Constantine the Great, but did not become a permanent method of legitimation till the time of Justinian. It was afterwards adopted by the Roman pontiffs and disseminated by the ecclesiastics throughout Europe. At the parliament of Merton, however, the doctrine met with a repulse from the barons of England; but though the English law was preserved inviolate, yet the ecclesiastics did not cease to press the point among the people, and to this day we may remark traces of the custom in some of the remoter districts of the island.

The doctrine was certainly no part of the ancient common law of Scotland any more than of England; but it is now settled law there, and its rise and establishment are unquestionably to be referred to the influence of the canon and civil laws in that country. The principle on which the doctrine rests was once supposed to be a fiction of law, that the marriage of the parents related back to their child's birth. If the parents could not then have legally married, or if a *mid impediment* intervened between the birth and the marriage, it was thought that the fiction was excluded, and that the previous issue would not be legitimated by marriage. But in one of these cases this theory has been overruled, and it has been decided that an intervening marriage of one of the parties to another person does not prevent the subsequent marriage of the two parents from legitimating their children born previously in bastardy. The sole restriction now admitted is that which was established simultaneously with the first introduction of the principle in the civil law, namely, that the parents must have been capable of contracting marriage with each other at the time of the birth of the offspring. It is not, however, decided whether, in the case of an intervening marriage of the father to another woman, by whom he has issue, the subsequent legitimation of bastards whom he had prior to that marriage will give them the rights of primogeniture over its issue. It is thought it would not, although, in the general case, a child legitimated takes precedence of its full brothers and sisters born in subsequent wedlock. If the father is domiciled in a country which does not admit the doctrine, legitimation will not follow from subsequent marriage; but the circumstance of the marriage taking place in such a country will not prevent legitimation from taking effect, if the father is domiciled in Scotland. In England the judges have held, that a child born in Scotland before marriage, and legitimated in Scotland by subsequent marriage, though in point of fact the first-born son, and in status and condition, by comity, legitimate in England, will not succeed to land in England.

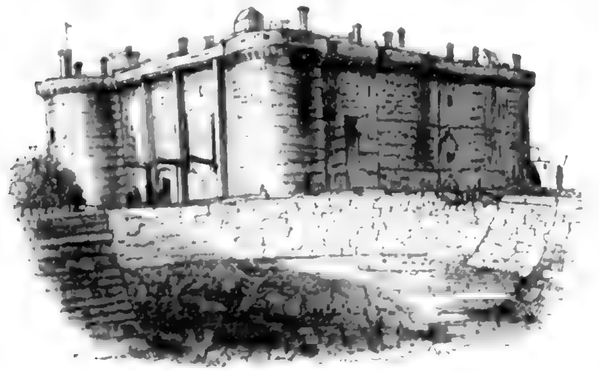
Legitimation *per rescriptum principis* proceeds on a less abstract and more generally-acknowledged principle than the preceding. Though, therefore, it is said to have been invented by Justinian, and copied by one of the popes of Rome, yet concessions in the nature of letters of legitimation are not peculiar to the Roman law. The form of these letters seems to have been borrowed by the Scots immediately from the old French jurisprudence: their clauses are usually very ample, capacitating the grantee for all honours and offices whatsoever, and to do all acts in judgment or outwith, and, in short, imparting to him all the public rights of lawful children and natural-born subjects, together with a cession of the crown's rights by reason of bastardy; but as the crown cannot affect the rights of third persons without their consent, letters of legitimation do not carry a right of inheritance to the prejudice of lawful issue.

As, in the Mosaic law, a bastard was debarred from the congregation, so, according to the canons, he is, in strictness, incapable of holy orders; and, indeed, it has been the policy of most nations to incapacitate bastards in divers ways, that if men will not be deterred from immorality by a sense of the injury accruing to themselves, they may by a consideration of the evils resulting to their offspring. But whatever may be the operation of those incapacities, they are felt by all to be wrongs inflicted on the innocent; and as Justinian properly observed, when he made legitimation *per subsequens matrimonium* a perpetual ordinance, 'indigni non sunt qui alieno vitio laborant.' Accordingly, such doctrines are now obsolete in Scotland. There is no distinction between a bastard and another man, in respect of power to dispose of his property in life or after death, and he may succeed to any estate, real or personal, by special destination. To his lawful children, also, he may appoint testamentary guardians; and his widow has her provisions like other relicts. It is to be noted, however, that in the eye of law a bastard is *nullius filius;* and being thus of kin to nobody, he cannot be heir-at-law to any one, neither can he have such heirs save his own lawful issue. Where a bastard dies, leaving no heir, the crown, as *ultimus hæres,* succeeds both to his personal and real estate, but commonly makes a gift of it to the person who would have been his heir if he had not been a bastard. As regards land held of a subject superior, the grantee must obtain from the Court of Session a decree declaring the bastardy, and thereupon he is presented by the king to the superior as his vassal.

But though bastards are legally *nullius filii,* yet the law takes notice of their natural relationship for several purposes, and particularly to enforce the natural duties of their parents. These duties are comprised under the term *aliment,* which here, as in the civil law, comprehends both maintenance and education; including under this latter term, as Lord Stair says (b. l. tit. 5, sec. 6), "the breeding of them for some calling and employment according to their capacity and condition." In determining who is the father of a bastard, the Scottish courts again proceed on the principles of the civil law. In Scotland there must first be semi-plenary evidence of the paternity, and then, when such circumstantial or other proof of that fact is adduced as will amount to *semiplena probatio,* the mother is admitted to her *oath in supplement.* The whole aliment is not due from one parent, but from both parents; and therefore, in determining what shall be payable by the father, the ability of the mother to contribute is also considered. The absolute amount of aliment, however, is in the discretion of the court, as is likewise its duration.

The mother of a bastard is entitled to its custody during its infancy; but afterwards the father may take the rearing of the child into his own hand, and may also nominate to it *tutors* in the event of his death.

BASTILE, or BASTILLE, the name used in France to denote a fortress or state-prison. There have been three of that name at Paris, the Bastile du Temple, the Bastile of St. Denis, and that of the Rue St. Antoine. We shall only treat of the last, which has obtained historical celebrity, and is usually denominated The Bastile. This fortress stood at the east end of Paris, on the north side of the Seine. It was originally intended for the protection of the city, but afterwards was used as a state-prison. Hugues d'Aubriot, Prevost des Marchands in the reign of Charles V., laid the first stone on the 22nd of April, 1369, by the order of that king. There had previously been a fortified entrance to Paris on the same spot, on a small scale, which was built by Etienne Marcel, the predecessor in office of Hugues d'Aubriot. The Bastile consisted at first of two round towers, with an entrance between them; afterwards, to render it stronger, two additional towers, parallel to the two first, were built, and the whole connected by walls. The building, however, was not completed till 1383, in the reign of Charles VI., when four more towers were added, of the same dimensions, and at equal distances from the first four, and the whole eight were united by masonry of great thickness, in which were constructed a great number of apartments and offices. The entrance to the city by the original gate was closed, and the road carried without the



View of the Bastile, from a Print in the British Museum.

building. In 1634 a fosse was dug round it, 120 feet wide and 25 feet deep; and beyond that a stone wall, 36 feet high, was built all round. Thus the Bastile became, from a fortified gate, one of the strongest fortresses of the kind in Europe. The towers contained several octagonal rooms one above the other, each having one window pierced in the walls, which were rather more than six feet thick. This window was without any glazing, was wide internally, but narrow like a loop-hole on the outside: in the centre was a perpendicular bar of iron, and two cross-barred gratings between that and the internal part. The entrance to each of these rooms was secured by double doors eight inches thick, strapped with iron, and placed at the distance of the thickness of the walls from each other. There were no fire-places or chimneys in these rooms. The only article of furniture, if it may be so called, was an iron grating, raised about six inches from the floor, to receive the prisoner's mattress, and prevent its decay from the damp of the stone floor. To each tower there was a way by a narrow winding staircase. The apartments constructed in the walls, connecting the towers, were larger and more commodious than the others, and were provided with fire-places and chimneys, but with similar precautions for preventing the escape of prisoners. They were usually assigned to persons of some importance, or to those who were treated with indulgence. The rest of the Bastile consisted of two open courts: the larger, 102 feet by 72, called the Great Court; the smaller, 72 by 42 feet, French measure, called the Court of the Well, was separated from the first by a range of buildings and offices, having a passage through them. The height of the building within was 73 feet, but greater on the outside next the fosse. (See the Plan in the British Museum.)

In modern times the establishment of the Bastile consisted of a governor, a deputy-governor or lieutenant du roi, a major, an aide-major, a physician and surgeons, a certain number (usually about 100) of invalid soldiers and Swiss in the pay of France to perform the military duty of the fortress, with turnkeys to watch over the prisoners, and cooks and other domestics. The office of governor was very lucrative; the pay and perquisites being supposed to amount to 60,000 francs per annum. Prisoners were almost always taken to the Bastile by an exempt of police and two or three armed men in a hackney coach, to avoid observation, and were conducted direct to the governor at his house, to whom the exempt delivered the *lettre de cachet* and took a receipt for it. The prisoner was then led into the body of the fortress, a sign being first made to all the soldiers on duty to cover their faces with their hats during his passage. This was invariably done whenever a prisoner entered or left the Bastile. The prisoners were subjected to frequent and minute interrogations, with a view to extort from them their secret, if they had any, the names of their accomplices, &c. Their treatment depended entirely on the will of the governor, who was interested in their being detained, as he contracted with the government for their maintenance, and derived a profit from it; and he being the only channel by which the prisoners could communicate with their friends or with the government, he could suppress their applications if he thought fit. We have the concurrent testimony of almost all the prisoners who have written their memoirs, that the food was bad and scantily supplied, and that all other necessaries were of the worst description. The duration of a prisoner's detention was arbitrary. No term was ever specified. The longest we have been able to discover, from the registers published after the taking of the Bastile, is that of Isaac Armet de la Motte, who was removed to Charenton (a lunatic asylum and prison), after a confinement in the Bastile of fifty-four years and five months. In this registry there are several others of thirty years and upwards. The first historical mention of any imprisonment in this fortress is that of Hugues d'Aubriot himself, who having given offence to the clergy, and being accused by them of blasphemy and impiety, was sentenced to be imprisoned for life, but being transferred to another prison, he regained his liberty in the insurrection of a faction called the Mailliotins. The only prisoners who ever effected their escape from the Bastile were two persons of the name of De la Tude and D'Aligre. They were confined together in one of the apartments constructed in the walls of the Bastile. By unravelling their linen, stockings, and other parts of their clothes, and by saving from time to time the billets of wood allowed for their firing, they contrived to make two ladders, one a rope-ladder, near 180 feet long, with rounds of wood covered with flannel to prevent any rattling noise against the walls; the other a wooden ladder, about 30 feet long, consisting of a centre piece, in joints to be fastened by tenons and mortices, and through which passed wooden pegs to hold it together. The first was to enable them to descend from the platform, or the top of the Bastile, into the fosse; the second to ascend the rampart into the garden of the governor. The ladders, as well as the tools they had formed for making them, were concealed, when the turnkeys visited them, under the floor of their apartment. They cut through the iron gratings in the chimney, which they ascended, and taking advantage of a dark night, got upon the platform. Having first lowered their wooden ladder, they fastened that of rope to one of the cannons of the fortress and descended into the fosse. Finding a patrole with a light in the governor's garden, they altered their plan, and with a handspike formed of one of the iron bars of the chimney grating, made a hole in the wall next the Rue St. Antoine, through which they effected their escape on the 26th of February, 1756. After the revolution of 1789 La Tude claimed and received these ladders, and they were publicly exhibited at Paris in the autumn of that year.

The Bastile was besieged and taken three times: in 1418, by the Bourgignons; in 1594, by Henry IV.; and on the 14th July, 1789, by the Parisians, from which day the French Revolution may be dated. Its demolition was decreed by the Permanent Committee of Paris on the 16th, and carried into immediate effect. The materials were employed in the construction of a new bridge, called the Bridge of Louis XVI., and there is not now remaining the smallest vestige of this edifice.

(Dulaure, *Histoire de Paris*; *Remarques Historiques sur la Bastille*; *La Bastille dévoilée*; *Mémoires de Linguet*; *Mémoires de la Tude*: and the various histories of the French Revolution.)

BASTINA'DO is derived from the Italian *bastone*, a stick, *bastonare*, to beat with a stick, &c. The word would have been more correct in the form bastonáta, but long use has confirmed our etymological error.

The bastinado is the chief governing instrument of a great part of the world, from Corea and China to Turkey, Persia, and Russia. It is administered in different ways, and called by different names, as the bamboo in China, the knout in Russia, &c.

According to our modern acceptation, the term bastinado does not include all these methods of stick-beating, but is confined to the Turkish and Persian method, which is to beat the soles of the feet with sticks. This excessively painful punishment is thus inflicted: Two men support between them a strong pole which is kept in a horizontal position; about the middle of the pole are some cords with two running knots or nooses; through these the naked feet of the sufferer are forced, and then made tight in such a manner that the soles are fairly exposed; the sufferer is then thrown on his back, or left to rest on his neck and shoulders with his feet inverted, which are forthwith beaten by a third man with a heavy tough stick. When the presiding officer or magistrate gives the word, the heavy blows cease, the maimed feet are cast loose from the cords and pole, and the victim is left to crawl away and cure himself as best he can.

In the Koran, stripes are prescribed as a punishment for some offences; murder was to be punished by death, and theft by the cutting off of the hand; but the bastinado became an early substitute, except in the case of highway robbery, when the offender is beheaded. By the letter of the penal code of the Ottoman empire, this punishment can only be inflicted on the *men* of the fourth and last class of society, which comprises the slaves, and the rayahs or tributary subjects of the empire, as Jews, Armenians, Greeks, &c. The other three classes, namely: 1. The Emirs, or issue of the race of the prophet Mohammed, and the Oulemas, or men of the law; 2. Public functionaries, civil and military; 3. Free citizens and private individuals who live on their rents or the proceeds of their industry, were all exempted by law from this cruel and degrading punishment; but the distinction was not very rigorously observed. By the original code the number of blows to be given was from three to thirty-nine; but a later clause permitted them, in certain cases, to be carried to seventy-five, and in practice, when the passions are inflamed, the Turks seem to dispense with the ceremony of keeping any account of the blows, and the men lay on till they are tired and the sufferer's feet reduced to an unsightly jelly.

The punishment, called *zarb* in Turkish, was generally inflicted in a summary manner, without examination or any form of trial, at the will or caprice of the sultan, his representatives, and the officers of justice and police. The most frequent dispensers of it were probably the Meuhtessibs, or the commissaries of police at Constantinople, each of whom, from time to time, and always unexpectedly, made the round of the quarter of the city assigned him, to see that the provisions were sold at the exact prices despotically and most absurdly fixed by the government, and to ascertain whether the weights and measures in use by the dealers were all just. This officer generally went on horseback, followed by an armed mob of irregular soldiers, and preceded by his bastinado-men (*falacadjis*), whose office was to execute the sentence the moment it was uttered. If the offending dealer were absent, then his shopman or journeyman was punished as his substitute, the commissary only requiring a victim *ad terrorem*, and not having patience to await the return or arrest of the master. The punishment was always inflicted on the spot, in front of the shop in the open street. Mr. W. J. Hamilton, in his 'Researches in Asia Minor, Pontus, and Armenia,' 1842, describes the punishment thus: "At Ispir" (not far from Kars) he says, "I was treated with a novel kind of entertainment, being roused by loud shouts and cries, and, looking round, I saw an unfortunate wretch lying on his back, with his heels up in the air, tied to a log of wood held up by two men, whilst others were inflicting the bastinado on his naked soles with great rapidity. On appealing to the governor to know the meaning of this proceeding, he was pleased to say that, in consequence of my presence, he would let the man off with a slight punishment, although he richly deserved more for his turbulent and quarrelsome behaviour, and ordered him to be set at liberty. On being released he could hardly move, and was roughly pushed out of the way into the house. He had been quarrelling with and striking an old woman; but the aggravation of his crime was having used indecorous language to a woman." Sometimes, instead of being bastinadoed, the offender or his journeyman (accomplice or not as it might be) was nailed by the ear to the door-post of his shop, and so exposed till sun-set; at other times there was substituted the punishment of the portable pillory, called a khang or cang by the Chinese (who make great use of it as well as of the bamboo), and styled tahtakulah by the Turks, who probably derived the instrument from the Tartars, who may either have borrowed the invention from or given it to the Chinese. [CANG.]

Under the old system the greatest violence, caprice, injustice, and corruption prevailed in the administration of justice. The man with money in his hands, could always save the soles of his feet by bribing the authorities, and the pain of the bastinado was seldom inflicted except on the very poorest of the *baccals*, or shop-keepers, and destitute and unprotected rayah subjects of the Porte. Sultan Mahmoud introduced some improvements; but under a despotic government, like that of Turkey, a summary and rapid mode of proceeding will always obtain more or less.

Although the privileges of the free Turks, or Osmanlis, civil and military, were not always respected, yet their pashas and men of authority or dignity were never subjected to the bastinado like the khans, begs, and others in Persia, where the shah would frequently have his vizir, or prime-minister, cudgelled on the feet in his presence, and the vizir would do the like with the highest of the ministers and officers under him. The Osmanlis were always a more sturdy and proud-spirited people than the Persians, and thought that only Jews, Christians, and other tributary subjects could be beaten with propriety. It appears, however, that in the time of Busbequius the Janissaries were "basted with clubs." That excellent old traveller says: "Their lighter offences are chastised by the club. . . . . And here let me acquaint you with the patience of the Turks in receiving that punishment: they will receive sometimes a hundred blows on their legs, their feet, and buttocks, so that divers clubs are broken, and the executioner cries out, '*Give me another!*' Yea, sometimes the chastisement is so severe, that several pieces of torn flesh must be cut off from the wounded parts before anything can be applied to cure them. Yet, for all this, they must go to the officer who commanded them to be punished; they must kiss his hand, and give him thanks; nay, they must also give the executioner a reward for beating them. . . . . . As some relief to their misery, they count those parts wounded with the rod or club to be free from any purgations and expiations after this life."

BA'STION. This term is applied to a species of tower, or rather to what has taken the place of the flanking towers in old fortresses, and which constitutes the principal member of the fortifications immediately surrounding a town, or position to be defended. The rampart by which it is formed is disposed on four sides of a pentagon, two of which, technically called the *faces*, meet in an angle whose vertex projects towards the country; the other two, denominated the *flanks*, connect the opposite extremities of the faces with the *curtain*, or that part of the rampart which coincides in direction with the sides of a polygon supposed to inclose the town; the fifth side of the pentagon is generally unoccupied by a rampart, and is called the *gorge* of the bastion.

From the infancy of the art of war the defenders of a fortress must have felt the necessity of having the walls disposed so as to afford means of observing the enemy when very near their foot; for, when these means were wanting, the enemy was enabled to plant his scaling-ladders against, or even to make a breach in the wall itself, with almost perfect security. This was inevitably the case when the ground-plan of the *enceinte*, or inclosing rampart, was a simple polygon, since the men stationed on the rampart for its defence, behind the parapet by which they were protected, were incapable of seeing the exterior ground which lay near the base of the walls. Thus, according to the old story in Pausanias (iv. 20), when the Messenians were besieged in their hastily erected fort on Mount Ira, the guards being driven from their posts by violent rains, and there being no towers or projections from the walls to shelter them, the Spartans gained possession of the parapets by escalade. To avoid such a surprise, it was the practice of the ancient engineers to construct either *machicoulis* on the top of, or projecting towers at certain intervals along the walls of fortresses, that from thence the besieged might get a view of and be able to annoy the enemy, when at the latest and most critical period of the siege the latter should have gained the otherwise undefended ground. The walls of Messene, built by Epaminondas (Paus. iv. 31), which were all of stone, and furnished with battlements and towers, were reckoned by Pausanias among the best specimens of Grecian fortification.

From the accounts given by ancient writers of their fortified places, and particularly from the precepts of Vitruvius ('Architectura,' lib. i. cap. 5), we learn that the projecting towers were sometimes square or polygonal, but generally circular, and that their distance from each other along the walls was regulated by the range of the weapons employed in the defence. In the fortifications of cities this distance seems to have varied from 80 to 100 paces, according to local circumstances, and the power of annoying the enemy by the arrows and javelins discharged from the towers; but, from the greater distance at which modern arms will take effect, the bastions, measuring from the vertices of their projecting or salient angles, are now generally, and agreeably to the rules of Vauban, placed at 360 yards from each other. It was a maxim with the ancient engineers that the projecting quoins of walls were detrimental to the defence, from the facility with which they might be destroyed by the battering-ram; and it is on this account that Vitruvius recommends the towers to be circular, or to have faces forming with each other obtuse angles. These towers were placed indifferently at the angles, or at any part of the line of the inclosing rampart: in the latter case, when they were of a square form, one side was parallel to the length of the rampart, and in the former, one face was almost always perpendicular to a line bisecting the angle between two adjacent sides of the polygon surrounding the town; that is, to what would be now called the *capital* of the bastion. It must have frequently happened, therefore, that this face was nearly unseen from any other part of the rampart, and that the enemy made his assault against it in order to avoid, as much as possible, being exposed to annoyance from the defenders of the neighbouring works. It is true that the smallness of the towers rendered it impossible for the enemy to be wholly concealed at their front; but the desire of entirely depriving the enemy of the benefit arising from the undefended nature of that ground probably induced engineers to dispose the faces of their towers like those of a modern bastion, so that two of them might form a projecting angle, whose vertex was on the capital.

There is no reason to believe that any material change took place in the manner of constructing the towers of fortresses during all the long period in which the ancient arms were employed; but it is easy to conceive that the invention of fire-arms would render it necessary to enlarge the tower for the purpose of receiving the guns, and to increase the thickness of the rampart, that it might be able as well to resist the concussion produced by the discharge of the ordnance placed upon it, as the shock of the enemy's artillery when fired against it. On this account, also, the ramparts were constructed of earth, and their exterior surface was formed at such an inclination to the ground as would enable it to stand unsupported, except where it became necessary to prevent an escalade; in which case a facing of stone, brick, or timber was made sufficiently high and steep to create a serious impediment to any attempt of that nature. An opinion that the bastions are the weakest parts of a fortress remained in force, however, long after the modern artillery was introduced in sieges. On this account they were at first made very small, when compared with the extent of the wall between them; and the line of each face, when produced towards the town, was made to intersect that wall, in order that the fire from the part intercepted between this produced line and the flank of the next bastion might co-operate with the fire from the latter in defending the ditch in front of the former bastion. But when the ramparts of a town were found to disappear almost instantly under the weight of shot discharged from large ordnance, it became necessary to employ ordnance of corresponding size on the walls; and the dimensions of the bastions were finally augmented to those at present assigned. The lengths of the faces vary from 100 to 120 yards, and the flanks are usually about 50 yards long; but the magnitude of the projecting angle in front, called the *salient* or *flanked* angle, to distinguish it from the angles formed by the faces and flanks which are denominated *shoulder angles*, evidently depends upon the angle of the polygon on which the *enceinte* is constructed. Each face of a bastion, if produced towards the town, now falls at the interior extremity of the flank of the collateral bastion, so that the flank defence of the faces of a bastion depends wholly upon the fire from the flanks of those on its right and left.

It is to Italy that we must look for the invention of the modern bastion: the wars which raged in that country from the commencement of the 12th century, and which were more systematically conducted there than in any other part of Europe, gave rise to this, as well as to many other inventions for military purposes. The precise date of its first formation is quite unknown; but if we omit the improbable story related by Folard, that the Turkish commander, Achmet Pacha, caused bastions to be constructed about Otranto, when he took that place in 1480, we may observe that it is spoken of under the name of *Balvardo*, as an improvement of great importance in the military art, by Tartaglia, in his 'Quesiti ed inventi diversi,' which was published in 1546; and in the same work is given a plan of the fortifications of Turin, which exhibits a bastion at each of the four angles of the rampart. Both Vasari, in his 'Lives of the Architects,' and Maffei, in his 'Verona Illustrata,' ascribe the invention to San Michaeli of Verona: one of the bastions of this city has on it the date 1527, and its construction is still ascribed to that engineer, who, in fact, was about that time employed in the erection or repair of several of the fortresses in Italy. From the word Balvardo, denoting a stronghold, the earliest French engineers gave to this work the appellation of *Boulevard*; and such is its designation in the treatise of Errard, which was published in 1594. The term *Bastion* appears to have been taken from the Italian writers, for Maggi, in his treatise 'Della Fortificatione delle Citta,' applies the term *Bastioni* to redoubts constructed of earth; and, according to Père Daniel, the French subsequently gave to such works the name of *Bastilles*, or *Bastides*. Froissart also uses these terms in speaking of the forts constructed during the siege of Ventadour by the Duc de Berri, under Charles VI. It should be remarked, however, that Errard applies the name of *Bastion* indifferently to works in the situation of those now so called, and to those to which the name of *Ravelin* is generally given; and doubtless it denoted originally any work of earth constructed on the exterior of one more ancient.

It appears that it had been the practice from the earliest times to form a rampart, or bank of earth, in front of the walls of fortresses, in order to secure the latter from the destructive effects of the ram; and it is easy to conceive that, by forming such a bank in front of the old towers of a place, so as to connect those previously existing in front of the adjacent curtains, the work would assume a figure like that of a modern bastion; and indeed would very much resemble one of the detached bastions in what is called the second system of Vauban; the original tower of the fortress occupying the place of the interior bastion of that system, and constituting a sort of *retrenchment* to the new work. The construction was proposed by Castriotto, in his elaborate work published at Venice in 1564, seemingly as if it had been his own idea; but probably he meant only to recommend the adoption of a kind of work which must have been then a novelty.

The Italian engineers, immediately after the invention of the bastion system of fortification, became celebrated for their skill in military architecture, and they seem to have been extensively employed in the construction or repair of fortresses beyond the Alps: one of the first of their labours in the north of Europe was the fortification of Landreci, with bastions, for Francis I.; and the like works were executed about New Hesdin, on the frontiers of Artois, for Charles V. In 1568, the Duke of Alva employed Pacciotto in the construction of the citadel of Antwerp, a regular fortress, whose bastions still exist within those subsequently erected at that place; and, during the reign of Elizabeth, Genebella was brought from Flanders to this country in order to superintend the formation of a bastioned *enceinte* about the ancient castle of Carisbrook, in the Isle of Wight.

Albert Dürer, the celebrated engraver, proposed, in 1527, to fortify places with circular towers only, like those of the ancients, but of larger dimensions; and in most of the plans published during the 16th century by Italian engineers, there appears to be a union of the old and new methods; for the angles of the polygons are furnished with round towers, and these are protected exteriorly by bastions.

The guns mounted on the flanks of a bastion, by firing along the ditch in front of the curtain and of the neighbouring bastions, created a serious impediment to the passage of the enemy across the ditch in attempting an assault, and it became necessary for him to silence that fire by a battery placed for the purpose in the direction of the ditch; but the establishment of this battery necessarily compelled the defenders to augment the number of guns in their bastions. To get room for these guns, engineers were induced to form their bastions with a double and even a triple flank on each side, the flanks receding from each other, from below upwards, in the manner of terraces, towards the interior of the bastion; and, to prevent the enemy from dismounting the guns in the lower flanks by other batteries raised in the prolongations of those flanks, it became necessary to mask them by extending the rampart of the face beyond them, and giving it a return towards the curtain; this return was frequently rectilinear, but generally in the form of an arc of a circle, like a portion of a round tower, and the projection with its return received the name of *orecchione* or *orillon*. Besides masking the lower flanks from the effect of any enfilading, or lateral fire, it concealed one or more guns on the upper flank from the fire of an enemy's battery directly opposed to that flank, while it permitted those guns to defend the main ditch and the breach made by the enemy in face of the collateral bastion. In Castriotto's work above mentioned he describes bastions with triple flanks and cavaliers, and *orillons*, similar to those of Coehorn; also many other works supposed to be modern improvements, such as *chemin des rondes*. [Berme]. Countermines, Casemates, Counterarched Revetments, and the Fausse Bray.

The desire of avoiding the exposure of the flanks of the bastions gave rise to the practice of making them form a right, and even an acute angle with the curtain; but a better judgment subsequently rejected this disposition, as the musketry fire from the defenders of the flank was thereby liable to injure the men stationed on the curtain. The lower flanks also were eventually suppressed, because they contracted too much the interior of the bastion to which they belonged; and because the enemy's fire, soon destroying the parapets of those above, masses of brickwork fell among the defenders below, and obliged them to quit their guns at the very time that their service was most required. The *orillons*, moreover, are now considered useless, as they contract the length of the flank; and the guns which they protect from a fire in their front are liable to be dismounted by a fire from their rear.

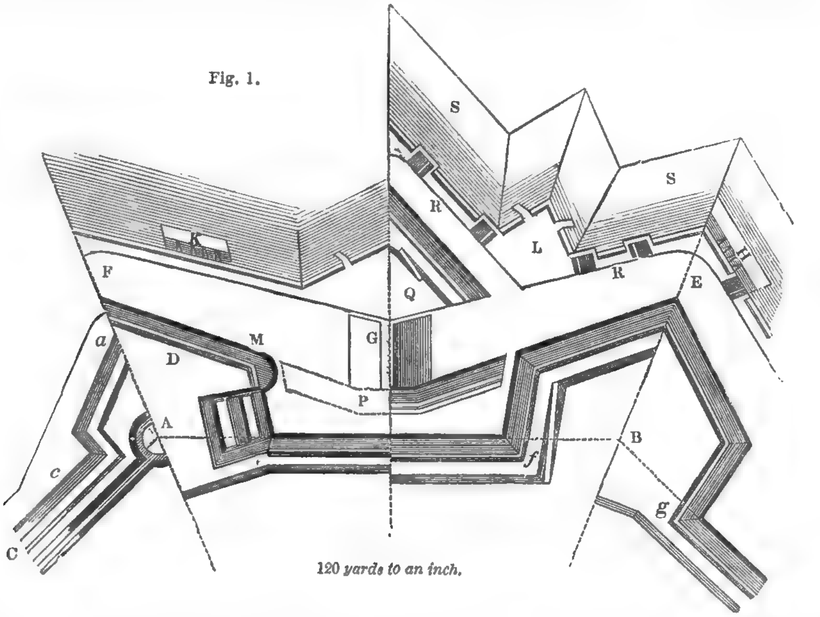
In what are called the second and third systems of Vauban, the principal bastions are detached from the *enceinte* by a ditch in their rear, and consequently the capture of those works would not immediately compel the surrender of the fortress. In these systems, a small bastion of brickwork, closed by a parapet-wall at its gorge, is constructed at each of the angles formed by the polygonal wall surrounding the place. The fire from the parapets of these tower bastions, as they are called, would have a powerful effect in preventing the enemy, after he has breached and stormed the great bastions, from erecting batteries in them to destroy the interior walls; and, in order to preserve the artillery of their flanks uninjured till the end of the siege, engineers placed it in casemates [Casemate], whence the guns might pour a destructive fire upon the assailants when crossing the ditch of the *enceinte*. In one of the systems of Coehorn, each principal bastion is attached to the *enceinte*, and contains an interior one for the purpose of prolonging its defence. At the shoulders of the former are constructed towers of masonry, serving as *orillons*, and containing galleries whose front walls are pierced with loop-holes, to allow a fire to be directed along the interval between the parallel faces of the two bastions.

Bastions are now made either solid or hollow: that is, either the interior is filled with earth up to the level of the platforms of the guns, or it is left coincident with that of the natural ground. Of the two methods, the former is generally preferred, because it affords some facilities for the formation and defence of interior parapets or retrenchments. In almost every system of fortification the ramparts of the faces and flanks of bastions have been made rectilinear on the plan; a few cases however occur in which the flanks have been curved, with their convexity towards the interior of the work. This seems to have been devised to allow room for a few more men to fire over their parapets than a straight wall could afford, and to prevent the distant batteries of the enemy from easily dismounting their artillery by firing along the interior side of the parapet. On some occasions these advantages may be worth obtaining, but as the soldier placed behind a parapet always fires nearly in a direction perpendicular to its length, it is evident that the curved flank may cause the lines of fire to tend towards the right or left of the main ditch, and thus endanger the safety of the defenders stationed in the neighbouring works.

The desire of lessening the effect of what is called the enfilading fire, or that which an enemy may direct along the interior side of any parapet, has led Bousmard to give a small curvature to the faces of his bastions, the concave part being towards the interior; but it is evident that, by this construction, the lines of fire directed from the collateral flank for the defence of the face, instead of grazing the latter in its whole length, can only be tangents to the curve, each line of fire meeting it in but one point. It is therefore probable that the injury inflicted on the enemy would be found so much less than that arising from the usual construction, as to neutralise entirely the advantage of the diminished enfilade fire of the enemy.

The destructive effect of this last mode of firing would be most effectually prevented by the formation of semicircular bastions, detached from the *enceinte*, in the manner proposed by Mr. Bordwine; but the ingenious author of that system is in consequence compelled to abandon, in a great measure, the advantage of having the exterior of his walls well defended from those which are in collateral situations. The batteries however which he proposes to raise in the interior of his

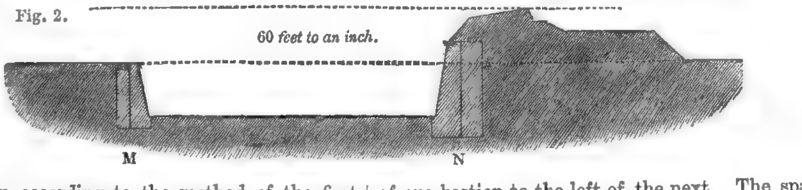
Fig. 1.



bastions cannot fail to produce a powerful defence towards the rear, for the rampart of his *enceinte*.

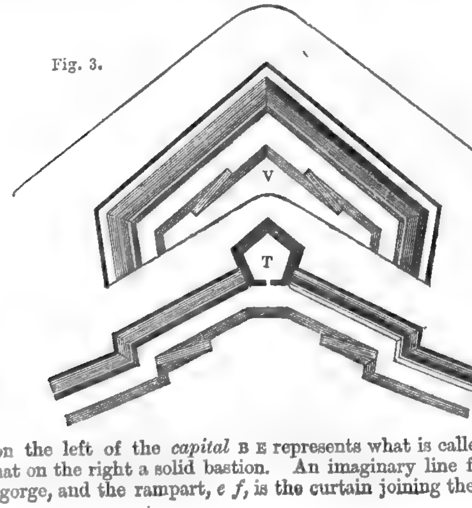
Fig. 1. The line A B represents one side of the polygon supposed to inclose the town fortified. The semicircular work at A is half a round tower; and A C is part of the curtain or connecting wall between two such towers, according to the ancient manner of fortifying places; *a c* represents a sort of *fausse braye*, or elevation of earth, protecting the ancient walls of a place; D represents half a bastion constructed

Fig. 2.



at the angle, A, of the polygon, according to the method of the first Italian and French engineers, with an orillon and triple flank. The pentagonal figure about B is the plan of a modern bastion, of which the

Fig. 3.



part on the left of the *capital* B E represents what is called a hollow, and that on the right a solid bastion. An imaginary line from *f* to *g* is the gorge, and the rampart, *e f*, is the curtain joining the right flank of one bastion to the left of the next. The space, F G E, is the main ditch; and H and K are respectively the positions of a counter and enfilading battery which might be constructed by the enemy to silence the fires from the triple flank of D. The outworks, P, G, Q, R, S, [TENAILLE, CAPONNIERE, RAVELIN, COVERED-WAY, and GLACIS] will be described under those words.

Fig. 2 represents a section supposed to be made from B to L, perpendicularly across the rampart on the left face of B, and the main ditch in its front. M and N are sections through the revetments, or walls which support the earth on the sides of the ditch.

In *fig.* 3, V represents the plan of a detached bastion; T is a tower bastion at an angle of the polygon which surrounds the place. The bastioned systems will be further treated under FORTIFICATION.

BA'TAVI, or **BATA'VI** (the forms Vatavi, Badai, and Betavi also occur in MSS. inscriptions), the name of the ancient inhabitants of South Holland, and some adjacent parts. The Batavi were a Germanic tribe of the race of the Catti, who, some time before the age of Cæsar, left their native district, and settled, according to Tacitus ('Hist.' iv. 12, 'Germ.' 129), "on the extreme borders of Gaul, such as they found destitute of inhabitants," but chiefly on an island formed by the northern arm of the Rhine (or Rhine of Leyden), the Vahalis, or Waal, and the Mosa or Maas after their junction, and the ocean; which island now constitutes part of the province of South Holland. The first mention of them is by Cæsar ('De Bell. Gall.' iv. 10), who calls their country by the name of Insula Batavorum, and appears to consider it as belonging to Germany, and not to Gaul; the limits of Belgic Gaul on that side being placed at the southern branch of the Rhine, or Waal, after its junction with the Mosa, or Maas. Cæsar did not carry the war into the country of the Batavi. Under Augustus the Batavi became allies of the Romans; they were exempted from taxes, and they furnished cavalry to the Roman armies on the Lower Rhine and in Britain, where detachments of them long continued to be stationed. Drusus, the brother of Tiberius, resided for a time among them, and dug a canal, Fossa Drusiana, which connected the Rhine with the modern Yssel. Besides the Batavi there was another people on the same island, probably in its north-western extremity, called by the Roman historians Canninefates. They were of the same origin as the Batavi (Tacitus, 'Hist.' iv. 15), but not so numerous, and their name became gradually lost in that of the larger tribe. Tacitus speaks highly of the bravery of both these tribes, and "for Germans" of their mental capacity.

The chief place of the Canninefates was Lugdunum Batavorum, now Leyden; and that of the Batavi was Batavodurum, afterwards called Noviomagus, and now Nymegen. This is Mannert's opinion, though others have placed Batavodurum at Duurstede, and made it a different place from Noviomagus. The other towns of the Batavi were Arenacum, generally supposed to be Arnheim, but placed by others near Werthuysen; Carvo, on the northern branch of the Rhine, probably near Arnheim; Grinnes, near the junction of the Waal with the Maas; Trajectum, the modern Utrecht; and Forum Hadriani, in the western part of the island near the sea. The name of the Batavi can be traced even now in that of Betuwe, which is a district of the ancient Batavorum Insula, between the Rhine, the Waal, and the Lek. Beyond the northern branch of the Rhine, and between that and the Flevium, or Yssel, in the province now called North Holland, were the Frisii and the Frisiaboni, tribes belonging to the great Frisian stock which inhabited the land north-east of the Yssel. Pliny places two other tribes, the Sturii and the Marsucii, on the islands off the western coast at the mouth of the Mosa, which islands now form part of Zealand.

After the death of Galba, the army of the Rhine having proclaimed Vitellius, and followed him on his way to Italy, the Batavi took the opportunity of rising against the Romans, whose alliance had become very burthensome to them. Claudius Civilis, a man belonging to one of their principal families, though bearing a Latin name, acted as their leader. At one time the insurrection seems to have spread among the neighbouring tribes of Germans as well as of Belgian Gauls, but the speedy return of the legions suppressed the movement. Civilis achieved many successes, and the Batavi, with their allies, fought bravely, but were at last subdued. According to Tacitus, however, they preserved their privilege of being exempt from taxation; they were a portion of the Roman empire; or, as he says, "free from all imposition and payments, and only set apart for the purposes of fighting, they are reserved wholly for the wars, in the same manner as a magazine of weapons and armour." (Gordon's transl. 'Germ.') As tools of this description they served under Hadrian in Mæsia, where they are stated to have swum across the Rhine in full armour. At this time, or as early as the reign of Trajan, the Roman domination was probably more complete, as we find in the Antonine Itinerary and the Peutinger Table, two Roman roads across the country, one from Lugdunum eastward to Trajectum, and following the course of the northern Rhine to its separation from the Vahalis, and another from Lugdunum southward across the island to the Mosa, and then eastward along the bank of that river and the Vahalis to Noviomagus. We also find places named after the emperors, such as Forum Hadriani, and fortified camps, such as Castra Batava, which some, however, suppose to have been the same as Batavodurum. (See Mannert, 'Geographie der Griechen und Römer.') There was another place in Upper Germany, or, more properly, in Noricum, called also Castra Batava, near the confluence of the Inn and the Danube, which was colonised by Batavi, apparently in conformity with the policy which led the Romans to transplant their subjects and allies from their homes to foreign countries. The Batavi were employed by Agricola in his wars in Britain. (Tacit. 'Agric.' xxxvi.) In some inscriptions they are called "friends and brothers of the Roman people," or of the "Roman emperors." The date of one of these inscriptions is determined by the name of the Emperor Aurelius. (Gruter. lxxi.)

In the latter part of the 3rd century, during the civil war which desolated the empire, the Salian Franks invaded the country of the Batavi, and established themselves in it. They armed pirate vessels, which were encountered and defeated at sea by Carausius. Constantius and Constantine waged war against the Franks of the Batavian island, but could not drive them out of it. The Franks lost it, however, under Julian, by an irruption of Frisians, who came from the northern country near the Zuiderzee, and drove the Salian Franks beyond the Maas. After this the Insula Batavorum formed part of the country called Fresia, which, in the time of the Merovingians, extended southward as far as the Scheldt. Under Charlemagne it formed a duchy bearing allegiance to the empire, "Ducatus Fresiæ usque ad Mosam." It afterwards became divided into Western Frisia, called Fresia Hæreditaria, which was subject to hereditary counts; and Eastern Frisia, or Fresia Libera, which remained independent. The Yssel formed the division between the two. About the 11th century we first find Western Fresia called by the name of Holland, some say from *hohl land*, "a low hollow land," and its counts took the name of Counts of Holland. The country of the ancient Batavi formed the southern part of their dominions; but the islands at the mouth of the Maas, and between it and the Scheldt, were the subject of frequent contentions and wars between them and the Counts of Flanders. (D'Anville, 'Etats formés en Europe après la Chûte de l'Empire Romain;' Meyer, 'Res Flandricæ.') Although the name Batavi has fallen into disuse, it has always been employed by modern authors writing in Latin, to signify the Dutch or Hollanders generally.

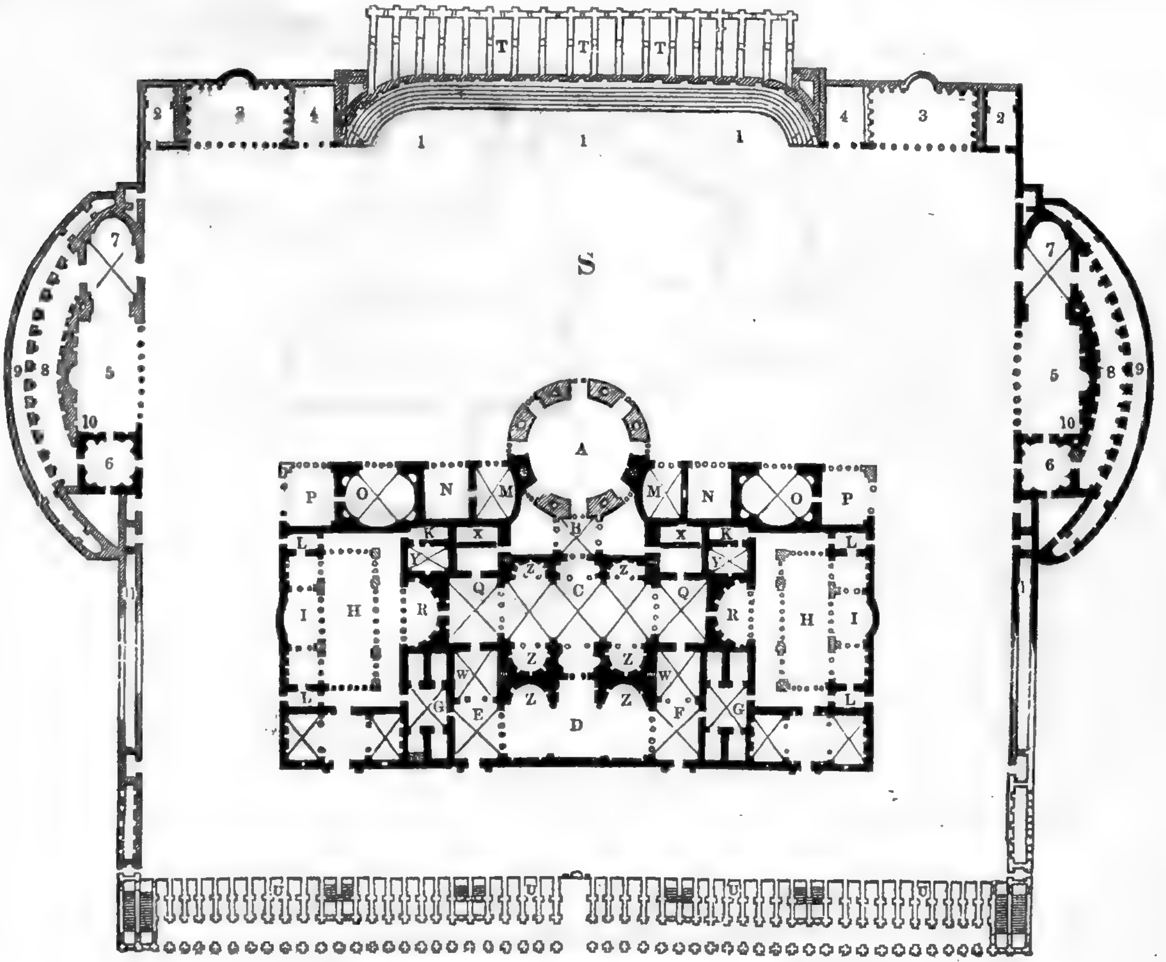
BATH, a place for the purpose of washing the body, either with hot, warm, or cold water: the word is derived from the Saxon bað. The Greek name is balaneion (βαλανεῖον), of which the Roman balineum, or *balneum*, is only a slight variation: the elements *bal* and *bad* in the Greek and English words are evidently related. The public baths of the Romans were generally called *Thermæ*, which literally means "warm waters."

The bath was also in common use among the Greeks, though we are not well acquainted with the construction and economy of their bathing-places. Homer often refers to the practice of bathing, but he speaks of the warm-bath as an unmanly habit ('Odyss.' viii. 248), and this view of the effeminacy of warm bathing was that held in the time of Demosthenes (Polyc.) At Athens there were both private and public baths: the public baths appear to have been the property of individuals, who kept them for their own profit or let them to others. (See Isæus, 'On the Inheritance of Dicæogenes,' cap. vi.; ditto 'of Philoctemon,' cap. vi.) Lucian, in his 'Hippias' (vol. iii. ed. Hemsterh.), has given a description of a magnificent bath. Though he does not tell us whether it was built in the Roman or the Greek style, we may safely conclude that he is speaking of a bath in a Greek city. His description is not precise enough to render it certain that this bath in its details agrees with those of Rome and Pompeii; but the general design and arrangement appear to be nearly the same.

We learn from Seneca that the Roman baths were very simple, even mean and dark, in the time of Scipio Africanus; and it was not until the age of Agrippa, and the emperors after Augustus, that they were built and finished in a style of luxury almost incredible. Seneca ('Epist.' lxxxvi.), who inveighs against this luxury, observes that "a person was held to be poor and sordid whose baths did not shine with a profusion of the most precious materials,—the marbles of Egypt inlaid with those of Numidia; unless the walls were laboriously stuccoed in imitation of painting; unless the chambers were covered with glass, the basins with the rare Thasian stone, and the water conveyed through silver pipes." These, it appears, were the luxuries of plebeian baths. Those of freedmen had "a profusion of statues, a number of columns supporting nothing, placed as an ornament merely on account of the expense: the water murmuring down steps, and the floor of precious stones." (Sen. 'Epist.' lxxxvi.) These baths of which Seneca speaks were private baths.

Ammianus Marcellinus reckons sixteen public baths in Rome. The chief were those of Agrippa, Nero, Titus, Domitian, Antoninus Caracalla, and Diocletian. These edifices, differing, of course, in magnitude and splendour, and in the details of the arrangement, were all constructed on a common plan. They stood among extensive gardens and walks, and were often surrounded by a portico. The main building contained large halls for swimming and bathing, some for conversation, others for various athletic and manly exercises, and some for the declamation of poets and the lectures of philosophers; in a word, for every species of polite and manly amusement. These noble rooms were lined and paved with marble, adorned with the most valuable columns, paintings, and statues, and furnished with collections of books for the studious who resorted to them. (See 'Pompeii,' published by the Society for the Diffusion of Useful Knowledge, vol. i.) These baths, which were called *Thermæ*, are now all in ruins. The best preserved are those of Titus, Diocletian, and Antoninus Caracalla. (See 'Life of Anton. Caracall.' by Æl. Spartianus.) We here subjoin a plan of the baths of Caracalla, which were finished, according to Eusebius, in the fourth year of that emperor's reign. These baths were among the most magnificent structures in existence. Mr. Fergusson says, that "even allowing for their being almost wholly of brick, and being disfigured by the bad taste inseparable from everything Roman, there is nothing in the world which for size and grandeur can compare with these imperial palaces of recreation." And he adds a comparison which will enable the ordinary English reader to form a better estimate of their size and character than he can readily do from mere description. He says: "St. George's Hall in Liverpool is the most exact copy in modern times of a part of these baths. The hall itself is a reproduction both in scale and design of the central hall of Caracalla's baths, but improved in detail and design, having five bays instead of only three. With the two courts at each end, it makes a suite of apartments very similar to those found in the Roman examples. The whole building, however, is less than one-fourth of the size of the central mass of a Roman bath, and therefore gives but little idea of the magnificence of the whole." (Fergusson, 'Hand-book of Architecture,' p. 333.)

The most complete and elegant baths had generally the following apartments: An apodyterium, or room for undressing; an unctuarium, for the ointments; a sphæristerium, or large room for exercises; a calida lavatio, or warm bath; a laconicum, or hot room for sweating; a tepidarium, or warm room with a tepid bath; and a frigidarium, which contained the cold bath: to these may be added rooms for feasting and conversation. (Cameron 'On Roman Baths.')



[Plan of the Baths of Caracalla from the measurements of Palladio.]

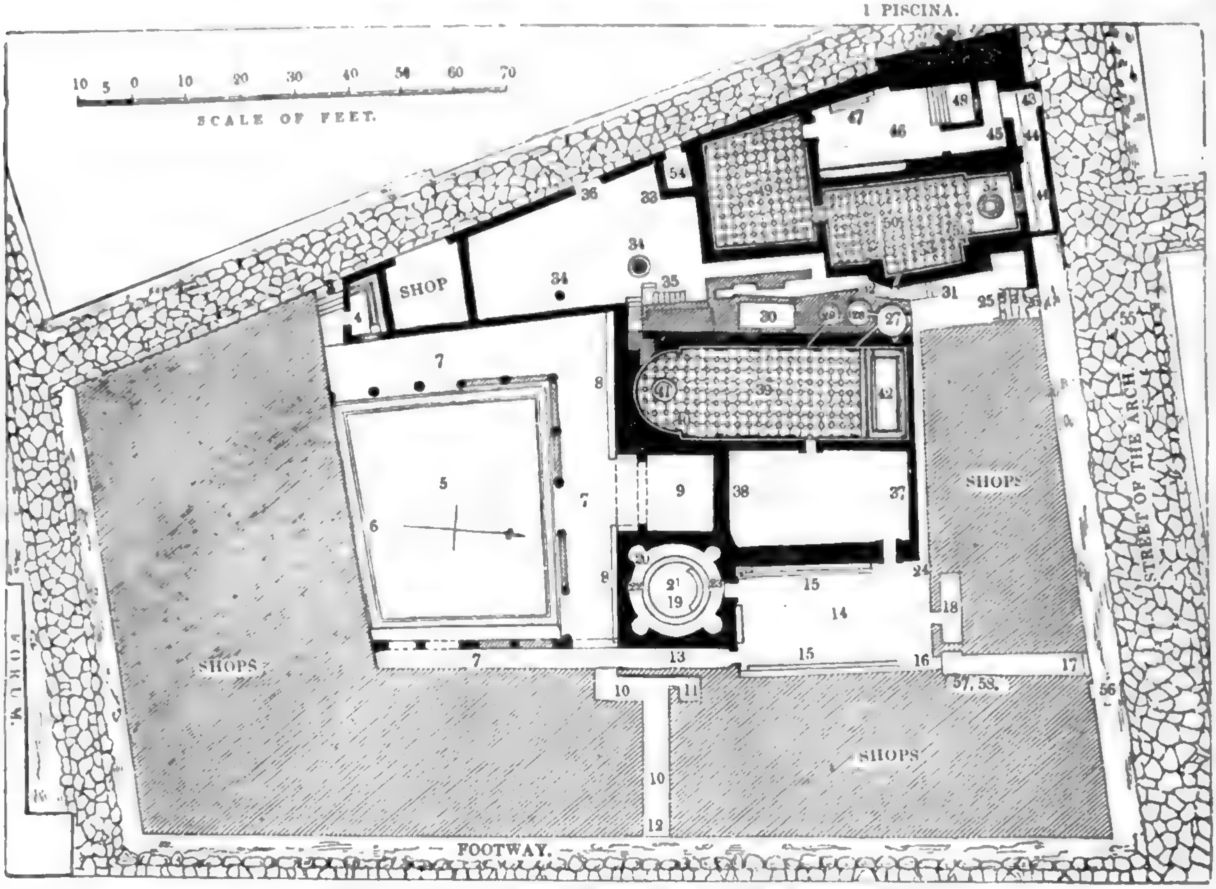
Scale of English Feet.
0 100 200 300 400 500

A, a circular room, over which was a roof of copper; B, the Apodyterium; C, the Xystus; D, the Piscina; E, Vestibules, on the side of the Piscina, which served for the spectators and to contain the clothes of those who bathed; F, Vestibules at entering the Thermæ; on each side were libraries; G, G, Rooms where the wrestlers prepared for the exercises of the Palæstra, with a staircase to ascend to the upper story; H, H, the Peristyles, which we find in all the Roman Thermæ, having in the middle a Piscina for bathing; I, I, the Ephebium or place of exercise; K, K, the Elæothesium, or Elæothekium (Ελαιο-θέσιον-θήκιον): L, L, Vestibules, over which there is another room with a Mosaic pavement; M, M, Laconicum; N, N, Warm Bath; O, O, Tepidarium; P, P, Frigidarium; Q, Q, Rooms for the spectators and for the use of the wrestlers; R, R, Exhedræ for the philosophers; S, Stadium; T, T, Places for heating the water; V, V, Cells for bathing; W, W, Rooms for conversation; X, X, Cisterns of three stories to receive rain water; Y, Y, the Conisterium; Z, Z, Recesses for ornament, and which served for the spectators to sit in; 1, Theatre for the spectators to see the exercises in the open air; 2. Apartments of two stories for the use of those who had the care of the baths; 3, 3, Exhedræ, where the gymnastic exercises were taught; 4, 4, Rooms for those who exercised in the Stadium; 5, 5, Atria to the academies; 6, 6, Temples; 7, 7, Academies; 8, 8, Arcades for the masters to walk in, detached from the noise of the Palæstra; 9, 9, Covered Baths; 10, 10, Stairs, &c., which led to the top; 11, 11, Stairs by which you ascend to the Palæstra.

Flaminius Vacca informs us that in 1471 there was to be seen in these baths an artificial island formed of marble, full of the remains of figures which had been carved on it. Near the island was a ship, with many figures in it, much broken. There was also a bathing vessel of granite. Two labra, of granite, found in the same place, are now employed as fountains in the great square before the Farnese Palace at Rome. In these baths were also found the Farnese Hercules and the great group of statues known by the name of the Farnese Bull. Besides the great granite column now in the palace of S. Lorenzo at Florence, Piranesi tells us that he saw, in the peristyle, two fountains enriched with the remains of bas-reliefs.

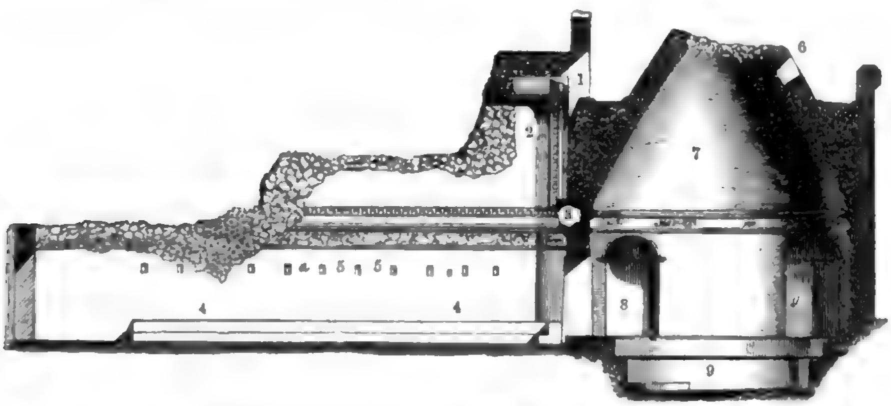
The provincial towns had also their baths, both public and private. The public baths of Pompeii, which were discovered in 1824, in a very perfect state, throw much light on what the Roman writers (and especially Vitruvius) have written on the subject. The following description of them is taken from the second volume of the 'Pompeii' (published by the Society for the Diffusion of Useful Knowledge), with a few verbal alterations, and some omissions: These baths occupy a space of about 100 feet square, and are divided into three separate and distinct parts. One of them was appropriated to the fireplaces and to the servants of the establishment; the other two were occupied each by a set of baths contiguous to each other, similar, and adapted to the same purposes, and supplied with heat and water from the same furnace, and from the same reservoir. The apartments and passages are paved with white marble in mosaic. It is conjectured that the more spacious of the two sets of baths was for the use of the men, the smaller for the women. Vitruvius (lib. v. cap. 10) says that the caldarium for the women should be contiguous to that for the men, and be exposed to the same aspect; for thus the same hypocaustum, or stove, may suffice for both. Annexed is the plan of these Pompeian baths, situated near the Forum.

The piscina or reservoir was separated at Pompeii from the baths themselves by the street which opens into the forum. The pipes which communicated between the reservoir and the bath passed over an arch thrown across the street. There were three entrances to the furnaces which heated the warm- and vapour-baths. The chief entrance opened upon a court of an irregular figure, fit for containing wood and other necessaries for the use of the establishment, covered in part by a roof; the rafters of the roof rested at one end on the lateral walls, and at the other on two columns, constructed with small pieces of stone. From hence a very small staircase led to the furnaces and to the upper part of the baths. Another led to the small room, called the præfurnium, into which projects the mouth of a furnace. In this room were the attendants on the furnace, or stokers (fornacarii), whose



[Plan of the Baths discovered in Pompeii, from the 'Museo Borbonico.']

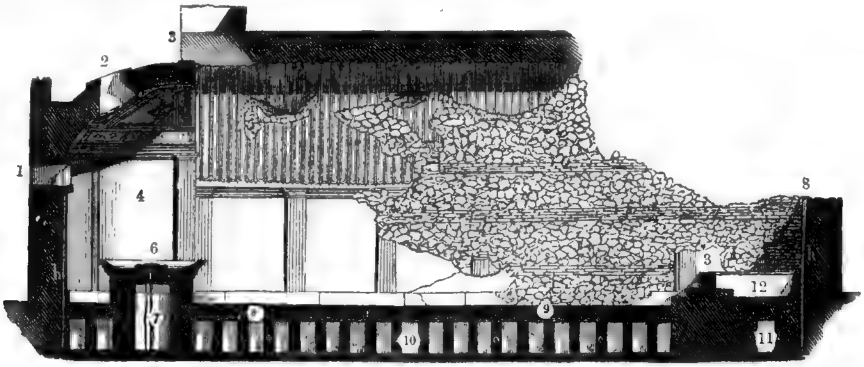
1, Piscina; 2, Street, over which was an aqueduct to convey the water from the Piscina to the baths; 3, Entrance to the baths of the men; 4, Watercloset; 5, Cortile, court, or vestibule to the baths; 6, Channel to collect the rain-water from the portico; 7, Colonnade round three sides of the vestibule; 8, Seats under the colonnade (*Scholæ*); 9, Oecus or exhedra; 10, Passage leading out of the baths; 11, Watercloset; 12, Entrance from the Street of Fortune; 13, Passage leading into the Apodyterium; 14, Apodyterium; 15, Seats; 16, Passage leading to the street; 17, Entrance from the Street of the Arch; 18, Wardrobe; 19, Frigidarium; 20, Niches in the Frigidarium; 21, Alveus or vase of the Frigidarium; 22, a bronze spout, through which the water ran into the Alveus; 23, Pipe out of which the water escaped; 24, Passages which lead from the Apodyterium to the furnaces; 25, Apartment for the stokers; 26, Doorway leading from this apartment to the Street of the Arch; 27, Furnace; 28, Calidarium, or boiler for hot water; 29, Tepidarium, or receptacle for tepid water; 30, Frigidarium, or reservoir for cold water; 31, Stairs leading to the boilers; 32, Passage which leads from the boilers to the court, where the fuel for the stoves was kept; 33, the court for fuel; 34, Columns which supported the roof of the court; 35, Stairs which lead to the arched roofs of the baths; 36, Door opening into the Street of the Forum; 37, Tepidarium; 38, Place where the bronze brazier was found; 39, Caldarium, having a suspended or hollow floor; 40, Laconicum; 41, Labrum: 42, Hot bath; 43, Entrance to the baths for the women; 44, Vestibule with seats; 45, Passage leading to the Apodyterium; 46, Apodyterium; 47, Seats in the same; 48, Frigidarium; 49, Tepidarium; 50, Caldarium with a hollow pavement; 51, Laconicum; 52, Labrum; 53, Hot bath; 54, a small room, use unknown; 55, Street, called the Street of the Arch; 56, Stairs; 57, 58, Two small voids without any communication.



[Section of the Apodyterium and Frigidarium of the Men's Baths.]

1, Window closed with one great pane of glass; 2, Decorated archivolt; 3, a place for a lamp; 4, Seats of the Apodyterium with a raised step, serving as a footstool; 5, Holes in which were pegs for the dresses; 6, a window; 7, Conical ceiling of the Frigidarium; 8, Niches; 9, Alveus or marble vase.

duty it was to keep up the fires. Here was found a quantity of pitch, used by the furnace-men to enliven the fires; the stairs in the room (25) led up to the coppers. The third entrance led from the apodyterium of the men's bath by means of a corridor (23). There is no communication between these furnaces and the bath of the women, which was heated *from* them. The furnace was round, and had in the lower part of it two pipes, which transmitted hot air under the pavements, and between the walls of the vapour-baths, which were built hollow for that purpose. Close to the furnace, at the distance of four inches, a round vacant space still remains, in which was placed the copper (*caldarium*) for boiling water; near which, with the same interval between them, was situated the copper for warm water (*tepidarium*); and at the distance of two feet from this was the receptacle (30) for cold water (*frigidarium*), which was square, and plastered round the interior, like the piscina or reservoir. A constant communication was maintained between these vessels, so that as fast as hot water was drawn off from the caldarium, the void was supplied from the tepidarium, which being already considerably heated, did but slightly reduce the temperature of the hotter boiler. The tepidarium in its turn was supplied from the piscina, and that from the aqueduct.



[Section of the Caldarium of the Men's Baths.]

1, Window; 2, a circular aperture by which the temperature was regulated; 3, another window; 4, Laconicum; 5, a place for a lamp; 6, Labrum; 7. Leaden pipe through which the water of the Labrum was either introduced or made its escape; 8, Hollow walls of the Caldarium; 9, Hollow pavement covered with Mosaic; 10, small piers which support the pavement; 11, the communication between the hollow pavement and the furnace; 12, Hot bath; 13, Steps to ascend the bath. ('Museo Borbonico,' vol. ii.)

The terms frigidarium, tepidarium, and caldarium were applied to the apartments in which the cold, tepid, and hot-baths were placed, as well as to the vessels already described under these respective names. The furnace and the coppers were placed between the men's baths and the women's baths, as near as possible to both, to avoid the waste of heat consequent on transmitting the fluids through a length of pipe. The coppers and reservoir were elevated considerably above the baths, to cause the water to flow more rapidly into them.

The men's bath had three public entrances (3, 12, 17). Entering at the principal one (12), which opens to the street leading to the forum, we descend three steps into the (5) vestibule, cortile, or portico of the baths, along three sides of which runs a portico (ambulacrum). The seats (8), which are arranged round the walls, were for the slaves who accompanied their masters to the baths, and for the servants of the baths themselves, to whom also the apartment (9) appears to have been appropriated. In this court was found the box for the quadrans, or piece of money, which was paid by each bather. Another door (17) leads to the same vestibule by means of a corridor. From the Street of the Arch (55) we proceed through the passage (17) into the apodyterium, or undressing-room (14), which is also accessible by another corridor (13) from a street called the Street of the Arch: a vast number of lamps were found here. The ceiling of this passage is decorated with stars. The apodyterium has three seats, made of lava, with a step to place the feet on; holes still remain in the wall, in which (it is conjectured) pegs were fixed for the bathers to hang their clothes upon. This room is highly decorated with stuccoed ornaments, relieved by colour. In the centre of the end of the room is a small opening or recess, once covered with a piece of glass; in this recess, as is plain from the appearance of smoke, a lamp has been placed. In the archivolt, or vaulted roof, immediately above, is a window two feet eight inches high, and three feet eight inches broad, closed by a single pane of cast glass two-fifths of an inch thick, fixed into the wall, and ground on one side: the floor is paved with white marble worked in mosaic, and the ceiling divided into panels. In this room there are six doors, one leading to the præfurnium; another into a small room, perhaps designed for a wardrobe; the third, by a narrow passage into the street; the fourth, to the tepidarium; the fifth, to the frigidarium; and the sixth, along the corridor to the vestibule or portico of the bath.

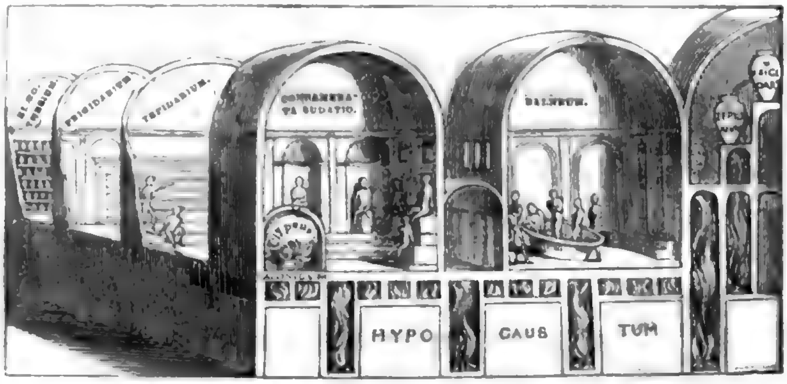
The frigidarium (19), or cold bath, is a round chamber, with a ceiling in the form of a truncated cone; near the top is a window from which it was lighted. The plinth, or base of the wall, is entirely of marble, and four niches are disposed round the room at equal distances; in these niches were seats (scholæ) for the convenience of the bathers. The basin (alveus) is twelve feet ten inches in diameter, two feet nine inches deep, and entirely lined with white marble; two marble steps facilitate the descent into the basin, and at the bottom is a sort of cushion (pulvinus), also of marble, to enable those who bathed to sit down. The water ran into this bath in a copious stream, through a spout or lip of bronze four inches wide, placed in the wall, three feet seven inches from the edge of the basin. At the bottom of the alveus is a small outlet, for the purpose of emptying and cleansing it; and in the rim there is a waste pipe to carry off the superfluous water: like the apodyterium, the frigidarium has been highly decorated, and is remarkable for its preservation and beauty. The tepidarium (37), or warm-chamber, adjoining the apodyterium, was so called from a warm, but soft mild temperature, which prepared the bodies of the bathers for the more intense heat of the vapour and hot-baths, and *vice versâ*, softened the transition from the hot-bath to the external air. This apartment is decorated with niches, divided by telamónes. [ATLANTES.] The room was highly enriched, both with stucco ornaments and colour, and was lighted by a window two feet six inches high and three feet wide, in the bronze frame of which were found set four very beautiful panes of glass, fastened by small nuts and screws, very ingeniously contrived with a view to their being removed at pleasure. In this room a large bronze brazier and three bronze benches were found. A doorway led from the tepidarium into the caldarium, or vapour-bath (39); at one end was the laconicum, where a vase (41) for washing the hands and face was placed, called labrum; on the opposite side of the room was the hot-bath, called lavacrum. Vitruvius, in explaining the structure of the apartments, says (cap. xi. lib. v.), "Here should be placed the vaulted sweating-room, twice the length of its width, which should have at one end the laconicum, made as described above, at the other end the hot-bath." This apartment is exactly as described, twice the length of its width, exclusively of the laconicum at one end, and the hot-bath at the other. The pavement and walls of the whole were made hollow, to admit the heat. Vitruvius never mentions the laconicum as being separated from the vapour-bath; it may therefore be presumed to have been always connected with it in his time, although in the thermæ constructed by the later emperors, it appears always to have formed a separate apartment. In the baths of Pompeii they are united, and adjoin the tepidarium, in this respect exactly agreeing with the description of Vitruvius.

The laconicum is a large semicircular niche, seven feet wide, and three feet six inches deep, in the middle of which was placed a vase, or labrum. The ceiling was formed by a quarter of a sphere; and it had on one side a circular opening one foot six inches in diameter, over which, according to Vitruvius, a shield of bronze was suspended, which, by means of a chain attached to it, could be drawn over, or drawn aside from the aperture, and thus regulate the temperature of the bath.

The laconicum at Pompeii does not exactly correspond with the laconicum painted on the walls of the Baths of Titus, and the laconicum described by Vitruvius. In the laconicum of Pompeii there is no cupola, such as we see represented in the painting of the Baths of Titus, nor aperture in the floor, although the flue in the hypocaustum runs beneath it. The brazen shield also is applied to regulate the escape of heat through the roof, not to admit or exclude the smoke and flame coming direct from the furnace, as appears to have been the case in the Baths of Titus. The latter was a clumsy and dirty way of heating a room, and strangely at variance, if it were really practised, with the finished elegance and luxury prevailing in every part of the Roman baths. The cupola in the Baths of Titus might, however, have been a contrivance similar to our modern stoves for heating with hot air. Where this cupola did not exist, the room probably was heated, as at Pompeii, by a large brazier. The proper meaning of the word laconicum, whether it should be applied to the cupola and clypeus, or to the room in which they were placed, has been much disputed. It seems pretty certain that the name laconicum, which meant in the first instance, the small cupola with the clypeus, became afterwards the name for that part of the room for which it was originally placed, even after the cupola had fallen into disuse, possibly from the discovery of a better method of heating the room.

Where the ceiling of the laconicum joined the ceiling of the vapour-bath, there was immediately over the centre of the vase, or labrum, a window three feet four inches wide; and there were two square lateral windows in the ceiling of the vapour-bath, one foot four inches wide, and one foot high, from which the light fell perpendicularly on the labrum as recommended by Vitruvius, "that the shadows of those who surrounded it might not be thrown upon the vessel." (Vitruv.)

The labrum was a great basin, or round vase of white marble, rather



Representation of Baths, from the paintings discovered in the Baths of Titus.

more than five feet in diameter, into which the hot water bubbled up through a pipe in its centre; it served for the partial ablutions of those who took the vapour-bath. It was raised about three feet six inches above the level of the pavement, on a round base, built of small pieces of stone or lava, stuccoed and coloured. In the Vatican there is a magnificent porphyry labrum, found in one of the imperial baths; and Baccius, a great modern authority on baths (see his work 'De Thermis,' Venice, 1588, and Rome, 1622), speaks of labra made of glass. This apartment, like the others, is highly enriched. The hot bath (42) on the plan, occupied the whole end of the room opposite the laconicum and next to the furnace. It was four feet four inches long, and one foot eight inches deep, constructed entirely of marble, with only one pipe to introduce the water, and was elevated two steps above the floor, while a single step led down into the bath itself, forming a continuous bench round it for the convenience of the bathers.

The Romans, who, according to Vitruvius, called their vapour-baths caldaria, or sudationes concameratæ, constructed them with suspended or hollow floors, and with hollow walls communicating with the furnace, that the smoke and hot air might be spread over a large surface, and readily raise them to the required warmth. The temperature was regulated by the clypeus or bronze shield already described, which acted as a ventilator.

In the baths of Pompeii, the hollow floors are thus constructed: Upon a floor of cement, made of lime and pounded bricks, were built small brick pillars, nine inches square, and one foot seven inches high, supporting strong tiles, fifteen inches square; the pavement was laid on these tiles, and incrusted with mosaic. The hollow walls, the void spaces of which communicated with the hollow of the suspended pavement, were constructed in the following manner: Upon the walls large square tiles were fastened, by means of iron clamps. These tiles were made in a curious manner; while the clay was moist, some circular instrument was pushed through the tiles, so as to make a hole, at the same time forcing out the clay and forming a hollow projection or pipe, about three inches long, on the inside of the tile: these being made at the four corners, iron clamps passed through them, and

[Transverse Section of the Apodyterium.]

fastened them to the wall. The sides of the apartments being thus formed, were afterwards carefully stuccoed and painted. The hollow space in the walls of the bath at Pompeii reaches to the top of the cornice; but the ceilings are not hollow, as in the baths which Vitruvius described, and which he distinguishes, for that reason, by the name of concameratæ. The ceilings of the apodyterium, tepidarium, and the caldarium are arched.

The women's bath resembles very much that of the men, and differs only in being smaller and less ornamented: for an account of it, we refer to Gell's 'Pompeii,' the 'Museo Borbonico,' and 'Pompeii' published by the Society for the Diffusion of Useful Knowledge.

Vitruvius recommends a situation for baths, which is defended from the north and north-west winds, and he says that the windows should be opposite the south, or, if the nature of the ground will not permit this, at least towards the south, because the hours of bathing among the Romans being from after mid-day till evening, those who bathed could by these windows have the advantage of the rays and the heat of the declining sun. Accordingly the baths just described have the greater part of their windows turned to the south, and are constructed in a low part of the city, where the adjoining buildings served as a protection from the north-west winds.

The baths at Rome were on a much larger scale. The public baths of Caracalla were 1500 feet in length, and 1250 in breadth: "at each end were two temples, one to Apollo, and another to Esculapius, as the tutelary deities of the place (*genii tutelares*), sacred to the improvement of the mind, and the care of the body; the two other temples were dedicated to the two protecting divinities of the Antonine family, Hercules and Bacchus. In the principal building were, in the first place, a grand circular vestibule, with four halls on each side, for cold, tepid, warm, and steam baths; in the centre was an immense square for exercise, when the weather was unfavourable to it in the open air; beyond it a great hall, where 1600 marble seats were placed for the convenience of the bathers; at each end of this hall were libraries. This building terminated on both sides in a court surrounded with porticoes, with an odeum for music, and in the middle a spacious basin for swimming. Round this edifice were walks shaded by rows of trees, particularly the plane; and in its front extended a gymnasium for running, wrestling, &c., in fine weather. The whole was bounded by a vast portico, opening into exhedræ or spacious halls, where the poets declaimed, and philosophers gave lectures to their auditors. This immense fabric was adorned, within and without, with pillars, stucco-work, paintings, and statues. The stucco and paintings are yet in many places perceptible. Pillars have been dug up, and some still remain amidst the ruin; while the Farnesian bull and the famous Hercules, found in one of these halls, announce the multiplicity and beauty of the statues which once adorned the Thermæ of Caracalla." (Eustace's 'Classical Tour,' vol. i. p. 226.) For an account of the baths of Titus and Diocletian, see the same author.

On entering these baths the bathers first proceeded to undress. They next went to the elæothesium (the oil-chamber), as it was called in Greek, or unctuarium, where they anointed themselves all over with a coarse cheap oil before they began their exercise. (Plin. xv. c. 4 & 7.) Here the finer odoriferous ointments which were used on coming out of the bath were also kept (Plin. l. ii. 'Epist.' 41), and the room was so situated as to receive a considerable degree of heat. This chamber of perfumes was full of pots, like an apothecary's shop; and those who wished to anoint and perfume the body received perfumes and unguents. In the representation of a Roman bath, copied from a painting on a wall forming part of the Baths of Titus, the unctuarium, called also elæothesium, appears filled with a vast number of vases. The vases contained a great variety of perfumes and balsams. When anointed, the bathers passed into the sphæristerium, a very light and extensive apartment, in which were performed the various kinds of exercises to which this part of the baths was appropriated. (Plin. lib. i, 'Epist.' 101.) When its situation permitted, this apartment was exposed to the afternoon sun, otherwise it was supplied with heat from the furnace. (Plin. l. 11. 'Epist.' 41.) After the exercise, they went to the adjoining warm-bath, wherein they sat and washed themselves.

The seat was below the surface of the water, and upon it they scraped themselves, or were scraped, with instruments called strigiles, which were usually made of bronze, but sometimes of iron or brass. (Martial, lib. xiv. 'Epig.' 51.) This operation was usually performed by an attendant slave. The use of the strigil is represented on a vase, found on the estate of Lucien Bonaparte at Canino. The vase is large and shallow, and painted within and without. (Vol. i. p. 183, 'Pompeii.') From the drawings on it we learn that the bathers sometimes used the strigils themselves, after which they rubbed themselves with their hands, and then were washed from head to foot, by pails or vases of water being poured over them. They were then carefully dried with cotton and linen cloths, and covered with a light shaggy mantle, called gausape. Effeminate persons had the hairs of their bodies pulled out with tweezers. When they were thoroughly dried, and their nails cut, slaves came out of the elæothesium, carrying with them little vases of alabaster, bronze, and terracotta, full of perfumed oils, with which they had their bodies anointed, by causing the oil to be slightly rubbed over every part, even to the soles of their feet. After this they resumed their clothes. On quitting the warm-bath they went into the tepidarium, and either passed very slowly through or stayed sometime in it, that they might not too suddenly expose their bodies to the atmosphere in the frigidarium; for these last rooms appear to have been used chiefly to soften the transition from the intense heat of the caldarium to the open air.

"It is probable that the Romans resorted to the baths, at the same time of the day that others were accustomed to make use of their private baths. This was generally from two o'clock in the afternoon till the dusk of the evening, at which time the baths were shut till two the next day. This practice however varied at different times. Notice was given when the baths were ready, by the ringing of a bell; the people then left the sphæristerium, and hastened to the caldarium, lest the water should cool. (Martial, lib. xiv. 'Epig.' 163.) But when bathing became more universal among the Romans, this part of the day was insufficient, and they gradually exceeded the hours that had been allotted for that purpose. Between two and three in the afternoon was, however, the most eligible time for the exercises of the palæstra. Hadrian forbade any but those who were sick to enter the public baths before two o'clock. The thermæ were by few emperors allowed to be continued open so late as five in the evening. Martial says, that after four o'clock they demanded a hundred quadrantes of those who bathed. This, though a hundred times the usual price, only amounted to nineteen-pence. We learn from the same author, that the baths were opened sometimes earlier than two o'clock. He says that Nero's baths were exceeding hot at twelve o'clock, and the steam of the water immoderate. (Mart. lib. x. 'Epig.' 48.) Alexander Severus, to gratify the people in their passion for bathing, not only suffered the thermæ to be opened before break of day, which had never been permitted before, but also furnished the lamps with oil, for the convenience of the people." (Cameron 'On Roman Baths,' p. 40.)

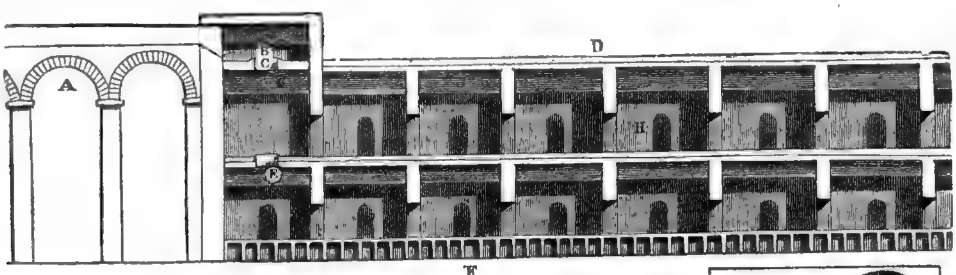
Coin representing the Baths of Alexander Severus.

The thermæ were constructed at a vast expense, and principally for the use of the poorer classes, though all ranks frequented them for the sake of the various conveniences which they contained.

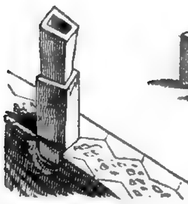
"Nothing relating to the thermæ has more exercised the attention of the learned than the manner of supplying the great number of bathing vessels made use of in them with warm water. For, supposing each cell of Diocletian's baths large enough to contain six people, yet, even at that moderate computation, 18,000 persons might be bathing at the same time; and as no vestiges remain of any vessels in the thermæ, to give the least foundation for conjecturing in what manner this was performed, it has been generally referred to the same process described by Vitruvius on a similar subject.

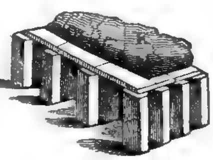
"Baccius has more professedly treated this subject than any modern author. He imagined that the water might be derived from the castella, which he observed to be situated without the thermæ; but as these castella were upon a level with the thermæ themselves, he thinks for that reason they were obliged to make use of machines to raise the water to such a height, as he observed it to have been by the ruins of Diocletian's baths. What led Baccius into this way of thinking was the number of pipes which he saw dug up under the open area, where there had never been any buildings, all of them surrounded with flues from the hypocaustum. He therefore imagined that the water was heated on the outside of the thermæ; but this supposition appeared so full of difficulties, as, upon reflection, to discourage him from inquiring any further into the subject." (Cameron.) By the assistance of two sections of the castella of Antoninus, drawn by Piranesi, Cameron endeavours to show the method adopted by the Romans to heat the large bodies of water which their extensive thermæ must have required.

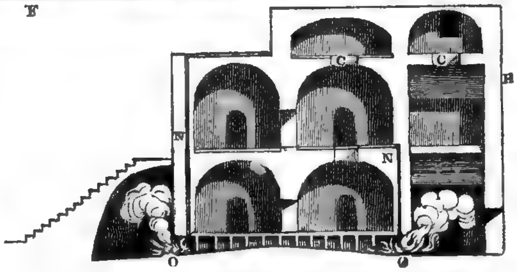
"To have a clear conception of the manner in which this was executed, it will be necessary to refer to a plate of these two sections.



Longtudinal Section of the Castellum, placed at T. T, on the Plan, cols. 993, 994.







Transverse ditto.

Flues in the floors and walls.—From Cameron. Specimen of Hollow Pavement.—From Cameron. Section of the Castellum of Antoninus Caracalla.—From Cameron.

"The castellum of the thermæ of Antoninus Caracalla was supplied with water by the aqueduct of Antoninus. Two of the arches of this aqueduct are represented at A; B is a cistern which received the water from the aqueduct; C is an aperture for permitting the descent of the water from the receptacle to the chamber below; D is a receptacle with a mosaic pavement, wherein the water was exposed to the heat of the sun; E is another aperture through which the water passed into the lowest chambers placed immediately over the hypocaustum; F, the hypocaustum; O O, doors for introducing the fuel. A transverse section through the middle of the same castellum is given at H.

"By the plan of this castellum, it appears that there were twenty-eight of these vaulted rooms placed over the hypocaustum; they were placed in two rows, fourteen on a side, and had all a communication with each other. The sections show, that over these were twenty-eight other rooms, having likewise a communication with each other, although only one of them had any communication with the chambers below, through the aperture at E. Upon the top of all was a spacious receptacle, not very deep, but extending the whole length of the castellum, in which the water was considerably heated by the influence of the sun, before it passed into the several chambers. This receptacle received its water from the cistern B, and not immediately from the aqueduct. The use of this cistern appears to have consisted in promoting a more gentle flow of the water into the receptacle, that its surface might not be ruffled by the least agitation, as that would very much have counteracted the purposes to which the receptacle was applied, nothing contributing so much as tranquillity in the water to acquire all the advantages from the influence of the sun its situation would permit. When there was no efflux from the inferior chambers, there could be no demands for water from the receptacle, which would have been liable to overflow were there not an aperture in the side of the cistern, through which the water ran off in different directions from that which was used for bathing. During all this time the water in the receptacle would be in the most perfect state of rest. The cistern, therefore, answered two material purposes, as it prevented any agitation in the water of the receptacle, and likewise carried off what was superfluous. The twenty-eight vaulted chambers, placed immediately over the hypocaustum, would now begin to be heated, which heat they would acquire so much the quicker, as only one of them had any communication with the external air by the apertures C and E. They therefore evidently were constructed upon the same principle as Papinius's digester, the strength of the walls and of the roof being sufficient to resist the force of the rarefaction of the air in the water, and consequently to prevent any loss from evaporation. Flues were still necessary to give the water a heat sufficient for bathing. The arched chambers were also suppled with flues, N N, from the hypocaustum, and served as a reservoir of tepid water for those below. The water they received was likewise heated by the sun. When the time for bathing was come, the cocks were turned to admit the hot water from the lower chambers into the labra of the baths, to which it would run with great velocity, and ascend a perpendicular height in the thermæ, equal to the surface of the receptacle in the castellum. The current would be accelerated by the great tendency the water would have to expand itself after having been confined in the chambers. The pressure of the column of tepid water was equal to, if not greater than the diameter of the column of hot water which ran out from the chambers below. To prevent the water cooling as it passed through the tubes underground, they were all carefully surrounded with flues from the præfurnium, so that these tubes were in the centre of a funnel, and always considerably heated before the water entered them. Each of these chambers was, within the walls, 49 feet 6 inches long, by 27 feet 6 inches wide, and about 30 feet high; the number of superficial feet in the bottom of the rooms being 38,115. If we allow 30 feet for the mean height, the whole quantity of water in these lower rooms will amount to 1,143,450 cubic feet, and the like quantity must be allowed for the upper rooms; allowing, therefore, 8 cubic feet of warm water as sufficient for one man to bathe in, and that water preserved in a bathing heat in the labrum half an hour, the whole consumption of hot water in this given time, for 18,000 people, would be 144,000 cubic feet. By this calculation there would be a sufficient quantity of water for three hours, or until five in the evening, for 108,000 people. The water, however, would gradually cool as it flowed in from the higher chambers.

"We have no intimation from the ancients when they first fell upon this expedient for heating such large bodies of water, whether it was the invention of the Romans or brought from the East. We may reasonably suppose, that as it was not necessary before the public warm-baths were built in Rome, it was not more ancient than the time of Augustus, in whose reign we are told by Dion Cassius (lib. lv.) that Mecænas first instituted a swimming-bath of warm water, or a calida piscina." (Cameron.)

But few Roman citizens in easy circumstances were without the luxury of a private bath, which was varied in construction according to the taste or prodigality of the owner. "Amongst many articles of luxury for which Pliny censures the ladies of his time, he takes notice of their bathing-rooms being paved with silver. Even the metal flues of the hypocaustum were gilt." (See Cameron 'On Roman Baths.' For an account of the private baths, see 'Pompeii,' vol. i. p. 199.)

The Persian manner of bathing, as described by Sir. R. Ker Porter, is in some respects not unlike that adopted by the ancient Romans. The Russian baths, as used by the common people, bear a close resemblance to the laconicum of the Romans. (See Tooke's 'Russia;' and BATHING.)

Ancient Roman baths have been found in several of the Roman villas in England; that at Northleigh in Oxfordshire, near Blenheim, is the most perfect. (See the account of the villa at Northleigh, Oxfordshire, by Mr. Hakewill.) Baths have been discovered also at Wroxeter in Shropshire, near Arundel in Sussex, and elsewhere. In the former, the suspended pavement was very perfect; in the centre of a chamber in that near Arundel is an octagonal bath sunk in the floor, the pulvinus of which is quite perfect. There are also some curious Roman baths at Vallogne in Normandy.

(Montfaucon, *Antiq.* t. iii. pl. 2; Cameron's *Roman Baths;* Gell's *Pompeii; Museo Borbonico*, vol. ii.; *Pompeii*, by the Society for the Diffusion of Useful Knowledge; Eustace's *Classical Tour;* Becker's *Gallus*, vol. ii.)

BATH, KNIGHTS OF THE, so called from the ancient custom of bathing previous to their installation. The origin of this order of knighthood has been described as of very remote antiquity; but as Camden and Selden agree that the first mention of an order of knights, distinctly called Knights of the Bath, is at the coronation of Henry IV. in 1399, there can be little doubt that this order was then instituted. That bathing had been a part of the discipline submitted to by esquires in order to obtain the honour of knighthood from very early times, is admitted; but it does not appear that any knights were called Knights of the Bath, till these were created by King Henry IV.

Froissart (see Lord Berners's 'Translat.,' edit. 1812, vol. ii. p. 752), speaking of that king, says:—"The Saturday before his coronation he departed from Westminster, and rode to the Tower of London with a great number; and that night all such esquires as should be made knights the next day, watched, who were to the number of forty-six. Every esquire had his own bayne [*bath*] by himself; and the next day the Duke of Lancaster made them all knights at the mass-time. Then had they long coats with strait sleeves, furred with mynever like prelates, with white laces hanging on their shoulders."

It became subsequently the practice of the English kings to create Knights of the Bath previous to their coronation, at the inauguration of a Prince of Wales, at the celebration of their own nuptials or those of any of the royal family, and occasionally upon other great occasions or solemnities. Fabyan ('Chron.,' edit. 1811, p. 582) says, that Henry V. on 1416, upon the taking of the town of Caën, dubbed sixteen Knights of the Bath.

Sixty-eight Knights of the Bath were made at the coronation of King Charles II. (See the list in Guillim's 'Heraldry,' fol. Lond. 1679, p. 107); but from that time the order was discontinued, till it was revived by King George I., under writ of Privy Seal, dated May 25, 1725, during the administration of Sir Robert Walpole. The statutes and ordinances of the order bear date May 23, 1725; and by them the constitution of the order, with the rites and ceremonies of the order, more particularly that of bathing, were entirely changed. By these it was directed that the order should consist of a grand master and thirty-five knights, a succession of whom was to be regularly continued. The order, besides the grand-master, are the dean, the genealogist and Blanc Coursier herald, the Bath king-at-arms, the registrar and secretary, the gentleman-usher of the scarlet-rod and Brunswick herald, and the messenger. The dean of the collegiate church of St. Peter, Westminster, for the time being, was appointed *ex officio* dean of the Order of the Bath, and it was directed that the other officers should be from time to time appointed by the grand-master.

On Jan. 2, 1815, the Prince Regent, being desirous to commemorate the auspicious termination of the long and arduous contests in which the empire had been engaged, and of marking, in an especial manner, his sense of the valour, perseverance, and devotion manifested by the officers of the king's forces by sea and land, directed that the order should consist of three classes; and on April 14, 1847, it was further enlarged by the constitution of it as a civil order.

The first class consists of knights grand cross, which designation was substituted for that of knights companions previously used. The knights grand cross, with the exception of the sovereign, princes of the blood-royal, and distinguished foreigners,—who may hold rank as honorary knights,—are not to exceed fifty for the military service, and twenty-five for the civil service.

The second class is composed of knights commanders, who have precedence of all knights bachelors of the United Kingdom: the number, for the military service, not to exceed one hundred and two, exclusive of foreign officers, who may be admitted into the second class as honorary knight commanders, or fifty for the civil service: but in the event of actions of signal distinction, or of future wars, the number of knights commanders may be increased.

The third class is composed of officers holding commissions in Her Majesty's service by sea or land, to the number of five hundred and twenty-five, and for the civil service of two hundred, who are styled Companions of the said Order, to take precedence and place of all esquires of the United Kingdom. No officer to be nominated a Companion of the Order, unless he shall have been specially mentioned by name in despatches published in the 'London Gazette' as having distinguished himself.

The badge of the order for the military classes is a gold Maltese cross of eight points, enamelled *argent*, in each of the four angles a lion passant guardant *or;* in the centre the rose, thistle, and shamrock issue from a sceptre between three imperial crowns, surrounded by the motto "Tria juncta in uno." Within a circle *gules*, surrounded by two branches of laurel proper, issuing from an escrol *argent*, inscribed "Ich dien," in gold letters. It is worn by grand crosses pendant from a red ribbon across the right shoulder; by knights-commanders pendant from the neck; and by companions at the button-hole.

The collar is of gold, weighing 30 ounces troy, composed of nine imperial crowns, and eight roses, thistles, and shamrocks, issuing from a sceptre, enamelled in their proper colours, tied or linked together by seventeen gold knots, enamelled white, and having the badge of the order pendant from it.

The star is formed by a gold Maltese cross, around which are rays of silver, and in the centre, within the motto, are branches of laurel, issuant as in the badge. That of the knights-commanders is in the form of a cross patée *argent*, with the centre as in that of the grand crosses, but without the Maltese cross *or* thereon.

The civil Knights Grand Crosses bear the old badge and star of the Order. The badge is of gold, and consists of a rose, thistle, and shamrock, issuing from a sceptre between three imperial crowns, encircled by the motto, "Tria juncta in uno," and is worn pendant over the right shoulder. The civil Knights Commanders wear the same badge pendant from the neck; and the civil Companions, one of a smaller size pendant from the button-hole, all by a red ribbon.

The star of the civil Knights Grand Crosses is of silver, with eight points or rays charged with three imperial crowns proper, upon a glory of silver rays, within a red circle, bearing the motto, "Tria juncta in uno." That of the civil Knights Commanders is of the same form and size as that of the military, but the laurel wreath and the motto, "Ich dien" are omitted.

BATHING means the temporary surrounding of the body, or a part of it, with a medium different from that in which it is usually placed. The means employed for this purpose are generally water, watery vapour, or air of a temperature different from that of the common atmosphere. The objects for which these are employed are usually the prevention of disease, the cure of disease, or the pleasure derived from the operation. To understand in what way these ends are accomplished, we must observe that the human frame is endowed with a power of maintaining, within certain limits, a nearly uniform temperature in whatever circumstances it is placed. The general temperature of an adult in a state of perfect health is from 97° to 98° of Fahrenheit's thermometer; that of a new-born infant about 94°. In some cases of disease the temperature rises far above this standard, even to 106°, while in others it sinks far below it. The power by which the body maintains a uniformity of temperature is the property of developing *animal heat*, the perfection of which function is intimately connected with the state of the nervous system, and through that with the circulation. When the body is well nourished and the circulation vigorous, the temperature is high, and nearly equal over all parts of the body, provided the supply of nervous energy be adequate. If anything impairs the vigour of the circulation generally, or of an artery going to a particular limb (as when it is tied in the operation of aneurism), the temperature of the whole or of the part will be low. On the other hand, if the whole nervous system be impaired, a lower temperature will prevail generally, and especially at the extremities; or if a particular limb, such as a paralysed limb, have an imperfect share of nervous energy, a lower temperature of the part will exist. The respiratory function is also intimately connected with the development of animal heat, and the skin assists in regulating it, especially in reducing it when too high. When the body is placed in a medium of a temperature much lower than itself, the heat is abstracted from the surface with more or less rapidity, according to the difference of temperature, and, if the medium be air, according to its state of humidity or dryness; the effect of which would be a reduction of the temperature of the whole body, were it not counteracted by an increased development of animal heat. Again, when the body is surrounded by a medium much higher than itself, the exhalation from the surface, both of the skin and lungs, is greatly augmented: that from the former being thrown off in the form of perspiration, that of the latter in the form of vapour. The evaporation attending these processes causes a reduction of temperature. As illustrations of the truth of these two positions, we need not do more than allude to the nearly equal temperature of the body maintained by Sir Joseph Banks, Sir Charles Blagden, Drs. Fordyce and Solander, in their experiments, when the heat of the room was 260° of Fahrenheit (see 'Animal Physiology, Library of Useful Knowledge,' part i. p. 3), and that maintained during the winter by the members of the expeditions under Captains Ross, Parry, and Franklin, when the thermometer frequently fell to 51° below zero of Fahrenheit.

In a moderate temperature the animal heat is generally prevented from rising too high by means of the *insensible* perspiration, the quantity of which varies with circumstances. According to the experiments of Seguin, the largest quantity from the skin and lungs together amounted to thirty-two grains per minute, or three ounces and a quarter per hour, or five pounds per day. The medium quantity was fifteen grains per minute, or thirty-three ounces in twenty-four hours. The quantity exhaled increases after meals, during sleep, in dry warm weather, and by friction, or whatever stimulates the skin; and it diminishes when digestion is impaired, and the body is in a moist atmosphere. These last-mentioned circumstances prove the sympathy which subsists between the skin and the internal organs. The skin must not, therefore, be regarded as a mere covering of the body, but as an organ, the healthy condition of which is of vast importance to the well-being of the whole frame, but especially of the stomach and lining membrane of the lungs, with which, as mucous membranes, it has the closest sympathy. It also sympathises with the kidneys, the quantity of discharge from which is regulated by the action of the skin. Hence in summer, when the perspiration from the skin is abundant, the secretion from the kidneys is less; and when, in winter, the secretion from the skin is diminished, that from the kidneys is increased.

The perspiration is the channel by which salts and other principles, no longer useful in the system, are removed from it. According to Thenard, it consists of a large quantity of water, a small quantity of an acid, which according to circumstances may be either the acetic, lactic, or phosphoric; and some salts, chiefly hydro-chlorates of soda and potass. Taking the lowest estimate of Lavoisier, the skin appears to be endowed with the power of removing from the system, in the space of twenty-four hours, twenty ounces of waste; the retention of this in the system is productive of great injury, and the inconvenience is only lessened by the increased action of some internal organ, which becomes oppressed by the double load thus cast upon it. Even the retention of the perspired matter close to the skin, from neglect of changing the clothes, is the source of many cutaneous diseases, particularly in spring and summer.

The great vascularity of the skin, and the manner in which the vessels of this part are influenced by affections of the mind, as in blushing, when it becomes red from more blood being sent to it, and during fear when less blood goes to it, and more to the vicarious organs, as the kidneys, point out how an exposure to a cold and damp atmosphere and how mental emotions are concerned in producing morbid action of this organ. The skin must also be regarded as a network of nervous filaments, and the most extensive organ of sensation: in this way it enables us to judge of heat and cold, though not with absolute certainty, as the sensation conveyed will depend upon the temperature of the medium in which the body or any of the limbs may have been placed immediately before. To understand this doctrine, it is necessary to be acquainted with the action of heat and cold on the human system; in our explanation of which, we will endeavour to be as concise as possible. We treat first of cold; in doing which it is necessary to distinguish between the immediate *primary* action of cold on the organ or part with which it is brought into contact, and the *secondary* action, depending upon the organic activity residing in the part, or that train of effects usually denominated *re-action*. The primary effect is always the same, consisting in the abstraction of heat from the part, and the consequent reduction of its temperature, while the internal development of heat becomes greater, so that the organic life strives ever to maintain an equilibrium between the conflicting powers, in order that it may not be limited or disturbed in its healthy action. Yet it must be remembered, that both the external and internal degree of the primary action of cold, as also the period in which it slowly or suddenly shows itself, and the time, whether longer or shorter, that it lasts, occasion a variety of effects, both in the part to which it is applied, and those more immediately sympathising with it, as well as in the whole system. The degree of primary action of cold can vary in endless degrees, from the lowest, where it scarcely affects the sensibility, to the highest, when it utterly destroys life. This difference of degree depends upon the concurrence of several circumstances, partly relating to the action of the cold itself, and partly to the nature of the organic life upon which the cold operates. The essential conditions which must be here borne in mind are, that the continual evolution of animal heat is closely connected with the development or exercise of animal life; and that the power or extent of action of external media, having a lower temperature than that of the animal they surround, depends less on the absolute degree of their temperature than upon the quantity of caloric which they can abstract in a given time.

The relative power and quickness of abstracting heat, with which different external media are endowed, depend upon different properties, such as their density, conducting power, capacity for heat, &c., and display themselves through the diversity of sensations which, at the same absolute temperature, they occasion. Thus, air at the temperature of 65° Fahr. feels pleasant, while water at the same degree feels somewhat cold. The organs of the body also differ in their power of sustaining the same temperature; hence, in the employment of vapour-baths, it is of importance to know whether the watery vapour is to be breathed or not, since, where it is to be breathed, the temperature must be much lower. The following table is given by Sir John Forbes as an approximation to what may be deemed correct as a measure of sensation in the cases where water and vapour are used.

	Water.	Vapour.	
		Not breathed.	Breathed.
Tepid Bath.	85° to 92°	96° to 106°	90° to 100°
Warm Bath.	92 „ 98	106 „ 120	100 „ 110
Hot Bath.	98 „ 106	120 „ 160	110 „ 130

As a full exposition of the subject of the temperature of animals is given under the article HEAT, ANIMAL, we must refer to it for further details, confining ourselves here to remark that the ultimate action of cold, when extreme, is a sedative to the nervous system, and alters the circulation from external to internal; and that moderate cold continued causes the same consequences as severe cold of short duration. (See Beaupré, 'On Cold,' Edinb. 1826.) Heat, on the other hand, is a stimulant to the nervous system, and alters the distribution of the blood from internal to external. Taking these principles as our guide, we proceed now to consider the different kinds of baths, and their action on the system in different states both of health and disease.

First, of water-baths. The common division is into cold and warm; but various subdivisions are formed, marked by a certain range of temperature, which are designated

1. The cold-bath, from	40°	to	65°
2. The cool	,,	65	,,	75
3. The temperate	,,	75	,,	85
4. The tepid	,,	85	,,	92
5. The warm	,,	92	,,	98
6. The hot	,,	98	,,	112

We shall treat first of the cold-bath, as applied to the whole surface of the body.

A healthy person upon entering a cold-bath experiences a sensation of cold, followed by slight shuddering, and if the immersion has been sudden, a peculiar impression on the nervous system, called a shock. The skin becomes cooler and paler, the respiration hurried and irregular, the action of the kidneys increases and the bladder contracts. In a few moments the colour and warmth return to the skin, and a glow is felt, especially if assisted by rubbing the surface. If the person remains more than five or ten minutes in the bath, the glow disappears, and paleness returns, which again gives place, though less quickly and perfectly, to a renewed glow. During the existence of the primary action of the cold, the bulk of the whole body, but especially of the more contractile parts, diminishes. Should the stay in the water be greatly prolonged, no reaction ensues, but a general feeling of chilliness prevails, with quick feeble pulse, convulsive breathing, cramps of the limbs, or fainting. If the person quit the bath after the few first minutes, as in prudence he should, the blood returns to the surface, accompanied with a sensation of pricking, itching, and sometimes throbbing of the arteries: the elasticity of the muscles being increased, more animal power is felt, accompanied with a general feeling of enjoyment.

Very young or feeble individuals are either incapable of bearing the shock, or the re-action is so slight that they cannot endure to stay in the bath beyond a very short time. If they unwisely stay or are held in the bath longer than one or two minutes, the heat never regains its proper height, the extremities remain contracted, and they, as well as the lips, nose, &c., are of a livid hue. In such cases, either artificial means must be used to bring about reaction, or the bath must be relinquished, as improper for such persons, as we shall show at a future part of our observations.

The phenomena just described generally accompany cold bathing; and it is clear that we can recognise in them a series of three or even four distinct actions: namely, 1st, the shock; 2nd, the cooling effect; 3rd, the contraction or astringent effect; and 4th, the re-action. Cold-bathing may be employed therefore in such a way as to insure the predominance of one action over any of the rest, according to circumstances, where all are not desired. They vary with the degree of cold and the suddenness of the application, as well as from the body being plunged into the water, or the water dashed against the body. Where the shock, as a stimulus to the nervous system, is desired, the water should be very cold, and where practicable should be dashed against the body, or, if the contrary, the stay in the bath should be momentary. This mode of using it may be either general or local. It has been employed generally—that is, the whole body exposed to the action of the water—in mania, with occasional success, and in the early stage of the common continued fever (under certain regulations, for which see Currie's 'Medical Reports'), sometimes with great success, cutting short the train of morbid actions which constitute the fever. It has been employed also in nervous affections, accompanied with a convulsive action, or deficient action of the muscular system, as in hysteria, in lock jaw (see Paper by Dr. Wright, 'London Medical Observations and Inquiries,' vol. vi. p. 143): in some cases of obstinate constipation, dashing cold water on the person, or the cold bath frequently repeated, has been of great service.

Its stimulating effect is sometimes best procured by a local application, in the form of a stream of water falling on the head, from a considerable height. The simplest example of this is the common practice of sprinkling the face with cold water in case of a tendency to faint; and in many diseases of the most dangerous character it is a remedy superior to any other. It is called the *cold dash*, or *douche*, or *douse*, and is beneficially employed in fever, particularly when the brain continues the seat of inordinate action of the blood-vessels, after depletion has been carried as far as prudence will allow. (See the instructive case of Dr. Dill in Dr. Southwood Smith's 'Treatise on Fever,' p. 398). It requires to be used with the greatest caution. Also in the state of stupor or *coma* which occurs in the last stage of *hydrocephalus acutus*, or water in the brain, it often succeeds in rescuing the patient from imminent danger. (See Abercrombie, 'On Diseases of the Brain,' first edit. 1828, p. 157.) Its utility is well known in the East in rousing drunken soldiers from their stupor so effectually as to enable them to rise up and appear immediately on parade. In the melancholy and mania which overtake habitual drunkards it is of great efficacy, and also in cases of loss of nervous power from excessive mental exertion. In apoplectic stupor it has also been very advantageously employed. In the sinking stage of croup, when all other remedies have failed, cold affusion has sometimes restored the functions of life to new action.

The cooling or refrigerating effect of cold bathing is most desired in diseases where the animal heat rises above the proper standard, as in fevers, both continued and eruptive, especially scarlet fever; also in some local inflammations, particularly of the brain. For the principles which should regulate our practice in this application we must refer to Dr. Currie and other writers, only remarking that, in the hot and restless stage of scarlet fever, when the heat is steadily above the natural standard, the skin hot and dry, and neither sleep nor perspiration can be procured, a plunge into cold water will be followed by both, to the relief and often recovery of the patient. (See Bateman 'On Cutaneous Diseases,' edit. 1829, p. 120.) In applying cold locally, as in inflammation of the brain, one rule is of the utmost importance to be observed, namely, that the application of the cold shall be continuous; therefore a second set of cold cloths or bags of ice should be applied before the former has become warm. This plan, especially pursued during the night, along with judicious internal treatment, will save many children from perishing under the most insidious and fatal disease of childhood—water in the brain.

The cases already mentioned are mostly acute diseases, where the cold affusion is employed to avert an imminent but temporary danger. It is generally in chronic diseases that the cold bath is employed for a length of time, and in these it is chiefly the secondary effect, the glow or reaction, which is desired. The rules to be observed in order to obtain this effect are founded upon the strength, which is generally inferred from the age, of the individual. The degree of reaction is, for the most part, dependent upon the coldness of the water and the length of time the person remains in the bath. Very cold water, in which the person remains but a short time, will in general produce a greater degree of re-action than a more moderate temperature in which he remains longer. But here everything depends upon the general power of the individual, the state of the system, especially of the skin at the moment of immersion, and the nature of the bath, according as it is fresh or salt water, and also the season of the year. As the immersion of infants and young children in tubs of water must be considered as bathing, we deem it necessary here to explain the principles upon which the temperature of the bath for them should be regulated, especially during winter. The experiments of Dr. Edwards (see Edwards 'On the Influence of Physical Agents on Life,' London, 1832) have proved that "the power of producing heat in warm-blooded animals is *at its minimum at birth*, and *increases successively to adult age*." It is clear therefore that water of a higher temperature than what feels cool to the hand of the nurse should be used, particularly in winter, when the power of regaining a proper degree of heat is necessarily less. The attempt to harden children by exposure to too great a degree of cold is of the most injurious nature; it either produces acute disease of the lungs, which are then very sensible to external impressions, or disease of the digestive organs, leading to disease of the mesenteric glands, scrofula, water in the brain, or, if they survive a few years, to early consumption. (See an illustrative instance in a young sister of Southey the poet, in vol. i., p. 28, of his 'Life,' 1st edit., 1849.) Delicate and feeble persons of all ages require a higher temperature of the bath, and a shorter stay in it than others. If the re-action does not speedily take place, means must be employed to ensure its so doing, or the use of the cold bath must be abandoned. A tepid or temperate bath may be used in the early treatment of feeble persons, and the cold bath gradually substituted for it, or a glass of wine, or, what is far preferable, strong coffee or chocolate may be taken before entering the bath. Where the arrangements are such as to admit of it, a brief stay in a warm bath before going into the cold has a good effect. Nor, in general, is danger to be apprehended from such a proceeding. Though in most cases moderate exercise is advantageous before bathing, unless the person has an opportunity of springing out of bed into the bath, still he should never think of undressing and going into the water when fatigued, or when the skin is covered with perspiration. It is a good rule to wet the head before taking the plunge. For a person in good health, early in the morning is the best time to bathe; for one more delicate, from two to three hours after breakfast is preferable; but no one should bathe immediately after a full meal, particularly if there be a tendency of blood to the head, and a disposition to apoplexy. Epileptics should rarely bathe, least of all in the sea.

Exercise while in the bath, such as friction of the limbs and chest, or swimming, is advisable, but not even this can prevent evil consequences if the bather remain too long in the water. To say nothing of the risk of cramps and convulsive action of the respiratory muscles, from the blood being pent up in the large internal vessels, which may occur while the person is in the water, the foundation may be laid for future internal disease if the blood do not soon revisit the surface, either from the natural powers of re-action, or from friction with coarse dry cloths. Friction should follow the use of the bath in most instances, except where the bath has been in the sea, in which case the salt particles if allowed to remain in contact with the skin, stimulate it more.

The cases of disease for which cold bathing is a valuable remedy are, morbidly increased irritability and sensibility, accompanied with general debility. If the sensibility be extremely high, it is best to begin with the tepid or cool bath, and pass gradually to the cold. Where there is a tendency to colds and rheumatism, the cold bath is an excellent preventive; for this purpose it should be used continually throughout the year, and the chest should be sponged with cold water, or vinegar and water may be substituted in winter, when there are not facilities for using the complete bath. Before beginning this practice, careful investigation of the state of the mucous membranes of the chest and intestinal canal should be made, as it will certainly prove hurtful where chronic inflammation of these organs exists. If tubercles are suspected to exist in the lungs, cold bathing should be dispensed with. Though cold bathing is very useful in a tendency to scrofulous diseases, it is very hurtful when these are really developed, though tepid and warm bathing are allowable.

Where the increased irritability shows itself in the mental functions or in the muscular system, as in hypochondriasis or hysteria, cold bathing is very useful; and especially in the hypochondriasis of literary persons, accompanied with a disposition to indigestion, and a dry harsh skin. In actual indigestion, especially if complicated with sub-acute inflammation of the mucous membrane of the stomach or intestines, cold bathing is very injurious.

In cases of torpor and loss of power, cold bathing is of much service; in a relaxed state of the skin, subject to debilitating perspirations, it is often the most effectual remedy; in weakness of the limbs, or of any member, and after sprains or paralysis, the local cold bath is very useful. The astringent as well as tonic effect of the cold bath is employed to prevent the prolapsus or descent of different parts: hence, in a tendency to hernia (or even when it has occurred, ice laid upon the tumour, and frequently renewed, has restored the bowel to its place, or at least warded off the inflammation till other means could be tried); in loss of power of the sphincter muscles, or of the contractile power of the bladder, pumping cold water on the back is very useful; but it should be used only for a minute at a time. In chronic hæmorrhages, cold applied locally or generally has a good effect.

The cold bath, like every other powerful agent, when improperly used, is capable of producing much mischief; in some states of the system it must be carefully avoided. In infancy and very advanced age it is less admissible than at other times, and even quite improper if the debility be great. It is inadmissible during, or immediately before, certain conditions of the female system; also when there is congestion of blood in the veins or internal organs: hence it is not suited to chlorosis. In any organic affection of the heart, or aneurism, it is altogether improper.

Of the cold shower-bath and douche we shall only observe here, that their effects are more speedy, and extend more to the internal organs: consequently they are only to be used for a very short time, whenever recourse is had to them. A glow of the surface is sooner felt after the shower than the common bath; and as soon as this is perceived the person should withdraw himself from the stream. If the douche falls upon the head, it produces almost instantaneous and most powerful effects. If its use be prolonged, it quickly lowers, then destroys the sensibility, induces faintings, and places the patient in the most imminent danger. Medical superintendence is therefore required through every stage of its employment.

When the body is surrounded by media of a temperature in some cases lower, and in some higher than its own, it receives caloric, instead of parting with it. The difference of density and humidity is the cause of its receiving it from some media which are of a lower temperature than its own, as well as from most which are higher. This depends upon the capacity for caloric, and the conducting power of the surrounding medium. Thus, dry air at 70° Fahr. will impart heat to the body, while water at 92° will abstract it, though water at 96° may impart heat. The tepid bath, therefore, being so close upon the limit of abstracting or imparting heat, cannot exercise a very powerful effect upon the function of the development of animal heat; neither does it much affect the circulation, which it rather retards than quickens; but its influence is mostly confined to the skin, which it cleanses, softens, and renders more fit to execute its duties. The cases in which the tepid bath is to be preferred to that of a different temperature, are those of a febrile character joined to an irritability of the skin, which is generally dry and harsh; some cutaneous diseases, where, by friction, the scales are removed and a new surface presented; and, lastly, as preparatory to the cold bath in delicate persons, or for those whose peculiarities of system render them unable to bear a warm bath of a high temperature. It is of much use in the form of tepid sponging of the surface in the advanced stage of fevers, and in convalescence from acute diseases. In this case vinegar is often added to the water with increased good effect. The natural tepid waters of Buxton furnish a most valuable bath for persons suffering from gout or rheumatism.

The primary effect of the application to the surface of the body of water of a temperature varying from 93° to 98°, is, in consequence of the communication of warmth, the same as that of dry heat, namely, a stimulating, enlivening, and expanding effect. Hence there is a quickening of the circulation and respiration, as well as the direction of a greater quantity of fluid to the surface, manifested by the swelling and redness of the part. There results also a freer and more lively action of the muscular system, and increased sensibility and activity of the nervous system. Diminished exhalation from the skin takes place, while a greatly increased absorption occurs: the exhalation from the lungs, however, is increased. An increased quantity of heat is thus introduced into the system, felt first in the superficial, but afterwards in the most internal parts of the body.

The secondary or ultimate effect is somewhat different. The increased action of the arteries gradually subsides, the pulse becomes fuller and slower, and the greatest quantity of the blood lodges in the veins, particularly in the great venous centres, such as the *vena porta* and the *liver*, which it stimulates to increased secretion of bile. Corresponding changes occur in all the other organs; and if the application of the warmth be continued for a longer time, the increased energy and elasticity of the muscles disappear, and a sense of fatigue, with atony, and a tendency to sleep, succeeds.

The final result of the action and re-action is an augmented secretion from the skin, and a corresponding diminution of urine, and of the secretion from the mucous surfaces.

The warm bath may be employed to effect two opposite ends, to stimulate or calm and soothe. It accomplishes the first when its temperature is high (98°), and its use is confined to five or ten minutes; the second when it is about 93°, and continued for three-quarters of an hour, or an hour. Employed in this last way, Marcard found that it always diminished the velocity of the circulation, and that the longer the bath was continued the slower the pulse became; also, that the more the pulse deviated from a state of health, the more it is diminished by the warm bath. The bath may even be prolonged till it induce fainting and other consequences of a depressed circulation. Short of actual fainting it may be beneficially employed to produce great relaxation of the muscular system, so as to enable dislocations or hernias to be more easily reduced. The state of relaxation bordering upon fainting is very favourable to the process of absorption; it may, therefore, be advantageously employed in dropsy arising from weakness of the absorbents. As the warm bath has generally the effect of equalising the circulation, and relieving internal congestion, it is much resorted to as a remedy in spasmodic and convulsive diseases; but here the utmost caution and discrimination are necessary. If the spasmodic actions result from an inflammatory state of any of the nervous centres, more harm than good will be done by a bath. The inflammatory condition must first be removed or greatly lessened by bleeding, purgatives, and other appropriate means, before the bath can be safely used. These cautions do not so strictly apply to the convulsive excitement which often precedes the eruption of small-pox, or even measles, which is often greatly relieved by the warm bath, which may also be repeated during the early stages of the eruption. (See Marcard, 'Uber die Bäder,' Hanover, 1793; or Duncan's 'Med. Comm.' 2nd Decade, part x. p. 153.) The convulsions of infants during teething are almost invariably attempted to be removed by the warm bath, but in many instances more harm than good is done. The condition of the brain must be carefully inquired into by the medical attendant, and the state of the gums investigated, before this measure should be had recourse to. If there be congestion of blood in the brain, this must be removed before any good can result from a bath, and after its removal the convulsive actions will generally subside. The same good effect will follow free scarification of the gums, if a tooth be preparing to protrude. [ANTISPASMODICS.] Even when the bath is properly applied, the good which might be derived from it is often frustrated by inattention or ignorance. The bath is prepared at random, and the temperature is never sufficiently regarded. If above 96°, it cannot fail to be injurious.

During the existence of all active inflammation, at whatever age, the warm bath may be pronounced an unfit measure; and even after the acuteness may have been reduced by active antiphlogistic means, the warm bath is a doubtful remedy, if we except a very few cases. Of these, inflammation of the peritonæum is the best marked exception; but even here the bath is a very secondary means towards lowering the action of the system, though it may assist the flow of blood from leech-bites, and may be continued till a tendency to faint show itself.

In acute rheumatism, after venesection, the warm bath may perhaps be employed, if we can ensure its being followed by copious perspiration. For this purpose the patient should have the bath close to his bed, remain in it for half or three-quarters of an hour, be well rubbed with warm flannel cloths, replaced in bed between warm blankets, take diaphoretic medicines, and drink bland warm fluids, such as gruel or weak tea, and maintain the perspiration for twenty-four or forty-eight hours.

In a disposition to gout or rheumatism the warm bath is more proper than when a paroxysm of these diseases occurs. In such cases the natural warm baths are preferable: those of the Queen's Bath, or Cross Bath, at Bath, the temperature of which is from 94° to 96°, are well calculated for such cases.

In few chronic inflammatory diseases are warm baths allowable, if we except some of those of the digestive organs, especially sub-acute inflammation of the mucous membrane of the stomach and intestines. Indigestion is often the most common symptom accompanying this state, and it is almost always benefited by a course of warm or tepid bathing.

The other states to which warm bathing is unsuited are great general torpor, but especially of the skin; also when there is a tendency to profuse secretion from the skin; when there is great plethora or fulness of the vascular system, especially of the veins; in tendency to active hæmorrhage; in aneurism, or any disease of the heart; also in cases of a tendency to apoplexy: lastly, in extreme atony, or excessive irritability of the nervous system. In the very extreme cases of derangement of the nervous system, the warm bath is unfit; in more moderate derangements of it, a more applicable or useful remedy cannot be found. In cases of nervous exhaustion from intense literary employment, or official or parliamentary duties, the warm bath is of great service, more particularly when, in addition to the warm bath, the cold douche is employed, directed upon the head for a few seconds, while the patient is in the bath. In the milder cases of mania it has been found of great use.

In cases of contractions of the joints from rheumatic or gouty inflammation, the warm bath, or, what is better, the local vapour bath, is of service in restoring the flexibility of the limb.

It may be briefly stated that the warm bath is much more serviceable when there is a tendency to disease, constitutional or accidental, or in convalescence, than in any other circumstances. It is therefore rather to be considered as a preventive than remedial measure. But its value in this point of view is very great; and it is to be regretted that it is not sufficiently appreciated and used. It is exceedingly beneficial as a means of allaying the irritation of the vascular system, which occurs in young persons disposed to consumption, when the disease is beginning slowly to impair the integrity and healthfulness of the lungs or other important organs. To prevent the development of the morbid deposit in the lungs is of infinite importance; and this will be best accomplished by keeping up a more vigorous action of the skin. The bath must be persevered in for a length of time. Proper bathing-rooms should exist in every well-constructed house; but as this is rarely the case in this country, a good substitute may be obtained by using some of the recently-invented bathing-machines, which combine facilities for using the different kinds of bath in the same apparatus. The best which we have seen is that made by Read, Regent Circus, which possesses an apparatus for applying the douche while in the warm bath, and may be used as a cold, a shower, a warm, a douche, or a vapour-bath. Baths should be attached to all large manufactories, as a refreshment for the workmen, to ensure cleanliness, and as a means of warding off many diseases: in lead-works, painters' and plumbers' establishments, they would protect the men from painters' colic; and in other establishments, they would preserve the workmen from many cutaneous diseases. "A multitude of chronic inflammations of the skin are produced by uncleanliness, or other agents, which directly irritate the skin; and it is to the want of cleanliness in the inferior classes that Willan attributes the frequency of cutaneous diseases in London. In France, advantages are placed within the reach of the poor, to which the rich alone aspire in other countries. The number of gratuitous baths which are given at the hospitals of St. Louis and La Charité is truly prodigious: in 1822 it amounted to 127,752 for the out-patients only of the hospital of St. Louis." (Rayer, 'On Diseases of the Skin.') Why some portion of the funds of hospitals and dispensaries in London and other large towns should not be applied in a similar way, we can see no good objection: there is as much philanthropy and benevolence in preventing disease as in curing it. The establishment of public baths in London and other large towns has proved of incalculable benefit. Where washhouses are attached to them, the advantage has been still greater.

A partial warm bath, such as the foot-bath, is of much service in warding off many complaints. After getting the feet wet, plunging them into warm water will often prevent any ill consequences; and even when the first chill and slight shiverings, which usher in colds, fevers, and other inflammatory complaints, have been felt, the disease may be cut short by the use of a foot-bath, continued till free perspiration occurs. In inflammatory diseases, where the head and throat are much affected, the employment of a foot-bath, at a later period, often gives great relief, by causing a revulsion of the blood from the upper to the lower part of the body.

Water of a temperature from 99° to the highest which can be endured, is termed the hot-bath. When a person in health enters such a bath, it greatly excites the nervous system, and, through that, the heart and arteries; causes heat and constriction of the skin, with disturbance of the internal organs generally, but especially those of secretion. This state of uneasiness is lessened by the breaking out of perspiration, which is succeeded by great languor, torpor, and disposition to sleep. In such a bath little absorption takes place through the skin, and the body is found to have lost weight. The hot-bath is a powerful stimulant, and can never be used by persons in a state of health. The same cautions which were stated under the head of the warm-bath apply to it in a greater degree. The few cases to which it is suited are chronic affections of the nervous system, such as paralysis, when all vascular fulness of the brain or spinal cord has been removed. The waters of the King's Bath at Bath, and some of the hot-baths on the continent, are very beneficially employed in such cases; but careful discrimination must be made to suit the temperature to the degree of sensibility remaining in the paralysed part. Where the power of motion is lost, the sensation is sometimes increased: here the hot-bath would be very hurtful. On the other hand, the sensation may be lost, while the power of motion remains: here equal care must be observed not to use too high a temperature. Erythema, erysipelas, mortification, or death may follow the use of too high a temperature or a stay too prolonged even in a proper temperature.

Sudden retrocession or repulsion of some cutaneous or eruptive diseases is relieved by the use of a hot-bath for a few minutes, the eruption often coming out favourably after it. Some chronic cutaneous diseases, in which great thickening or torpor of the skin exists, are benefited by the hot-bath.

Vapour-baths are either natural or artificial. Several natural vapour-baths exist in the Neapolitan States, in Switzerland (Pfeffers in the country of the Grisons), and in Ischia. The artificial vapour-baths are much in use in the East and in Russia, where they are public, or intended for several persons to use at the same time; and occasionally in Britain, where they are always solitary or for a single individual. The Russian baths are described in Lyall's 'Character of the Russians,' pp. 112-115. The bathing-room contains tiers of benches, like an amphitheatre, the seats nearest the bottom being the coolest, those higher up hotter. The temperature varies from 112° to 224°. Persons commencing the use of such baths occupy the lower seats, and ascend as they become accustomed to them. While exposed to the vapour, the body is washed or rubbed with soap or bran, and beaten with fresh birch-twigs. The head is surrounded with a cold cloth, or cold water is dashed over the head. When the person does not wish to breathe the heated vapour, a sponge which has been dipped in cold water is held to the mouth and nose. On first employing the vapour-bath, the person usually remains about fifteen minutes, but afterwards three-quarters of an hour, and at Pfeffers, the temperature of which is only 100°, sometimes four, eight, ten, or sixteen hours. After coming out of the bath, the bather goes into a room heated with dry air, where he is rubbed, puts on a flannel dress, and then reposes upon a couch for some time, where he may drink warm drinks to promote the perspiration.

"As soon," says Dr. E. D. Clarke, "as the inhabitants of these northern nations have endured the high temperature of their vapour-baths, which is so great that Englishmen would not conceive it possible to exist an instant in them, they stand naked, covered with profuse perspiration, cooling themselves in the open air. In summer they plunge into cold water, and in winter they roll about in the snow, without sustaining injury, or even catching cold. When the Russians leave a bath of this kind, they moreover drink copious draughts of mead, as cold as it can be procured." ('Travels in Russia,' part. i. p. 143). The absence of all risk in exposing the person to such extremes of temperature is explained by the experiments of Dr. Edwards, who found that "after an exposure to cold, sufficient to diminish the power of producing heat, continuance in a high temperature tends to the recovery of this power; for in exposing animals to successive applications of cold, their temperature will fall the more slowly the longer they shall have been subjected to the influence of warmth. It follows, therefore, that the effect of the application of a certain degree of heat is continued after the cessation of the cause. Hence, we see that those who are liable to frequent exposure to severe cold are rendered more capable of supporting it, by subjecting themselves in the intervals to a high temperature,—a practice adopted by northern nations, and justified by facts." (Edwards on the 'Influence of Physical Agents on Life,' p. 125.)

The vapour-bath is distinguished from all other means of introducing more heat into the body, chiefly by the circumstance, that as a portion of the vapour is converted into water, by coming in contact with the surface of the body, it communicates a quantity of sensible caloric to it. It is without doubt the most powerful means of supplying a great heat to the greatest portion of the surface of the body, internal as well as external; for when breathed, the extensive surface forming the interior of the lungs is influenced by it in the same way as the skin. On the skin it exerts a peculiar influence. It does not cause that constriction of the skin, which follows the application of dry air, nor does it exert that pressure upon the surface, which, in the case of warm water, retards the breaking out of the perspiration. On the contrary, moisture of the skin, followed by profuse perspiration, occurs immediately upon entering the vapour-bath.

In Russia, where such baths are used on a large scale, their employment is not found to be productive of weakness. The subsequent exposure to cold restores the tone of the skin which had been lost, and the process leaves the person with a general sense of good health, strength and power, both of the internal organs and of the skin. "These practices," says Dr. Clarke, "seem to delight them, and to add strength to their constitution."

The vapour-bath, by attracting the blood more speedily to the surface, and by being followed by more profuse perspiration, is more powerful than the warm water-bath. It is employed as a remedy in gout and rheumatism, and in the numerous consequences of these when they have assumed the chronic form. Many cases of rheumatic and gouty contraction of the joints have been removed by persevering in the use of vapour-baths, as employed by the continental nations. In scrofulous diseases, especially when they affect the skin and the glands, benefit is derived from the vapour-bath, unless there be a manifest tendency to active inflammation, and great irritability of the nervous system. In some chronic affections of the nervous system, especially when connected with the repulsion or imperfect development of cutaneous diseases, the vapour-bath is of great use; and also in some affections of the respiratory organs, such as dry catarrh, asthma, spasms of the muscles of respiration, if these are not complicated with inflammation or organic disease of the lungs or heart.

The use of the vapour-bath would be found to ward off many acute diseases resulting from exposure to cold, if had recourse to immediately after exposure to the exciting cause; as after travelling, or falling into the water in winter.

The local application of warm vapour is very serviceable in many recent diseases. Catarrhs, sore throats of an inflammatory kind, inflammations of the eyes and ears, are greatly alleviated by such means. But when the lungs are inflamed, though Mudge's or other inhaler is much recommended, yet the effort required to draw in the vapour is injurious. The head, from which a flannel cloth may fall down in such a way as to hinder the vapour from escaping, should be held over a bason full of warm water, and the vapour inhaled in the ordinary mode of respiration. The vapour-bath is very improper for plethoric persons, those predisposed to congestion, or to apoplexy, and also for individuals in a state of great debility.

The employment of heated air, as an application to the body, causes the primary action of heat to manifest itself more than the secondary. The hot-air bath is therefore powerfully stimulant to the skin and nervous system, and is of great service in all cases where the production of animal heat is less than natural, as in the cold stage of fevers, and exhaustion of the nervous power. It has been employed beneficially in congestive fever, and after great and continual mental exertion. It proved less useful in the Asiatic cholera than was anticipated. A convenient apparatus for applying it was invented by the late Dr. Gower, called a *Sudatorium*.

Medicated baths rarely possess greater power than that possessed by the water alone; but there are a few exceptions. The admixture of common salt makes the water more stimulating and tonic.

Sulphurous vapour-baths fall under the head of medicated baths, and a few remarks may be here made respecting them. Nightmen, and other individuals who live much in an atmosphere charged with sulphurous exhalations, are rarely affected with chronic diseases of the skin, while other trades seem to predispose to their development, such as the baker's itch and grocer's itch. It is chiefly for the cure of cutaneous diseases that the sulphurous vapour-baths are employed. In many of these they are very useful, especially those belonging to the genus scabies and genus impetigo of Bateman. A caution is requisite for their safe employment, that the vapour should not be applied to more than a fourth part of the body at one time, lest the disease should be suddenly cured, and the internal organs suffer by the repulsion. The person who uses the sulphurous vapour-bath must be careful not to breathe any of the vapour. This kind of bath has been used in rheumatic affections, some diseases of the stomach, and in chronic paralysis. It may sometimes be a useful addition to internal treatment, but alone can be of little avail, till the state of the internal organs be improved, especially the liver, the action of which is almost always faulty in gout and rheumatism.

The nitro-muriatic bath of Scott is of use in chronic inflammation of the liver, such as occurs in warm climates. The iron-baths in Nassau and the Hartz are more tonic than the simple cold-bath, but none of the iron can be absorbed at the low temperature of these baths; it is only, therefore, by their direct action upon the skin, and the sympathies of this with the internal organs, that they are more beneficial. We have no knowledge of the effects of the mineralised mud baths, called by the Italians *Lutatura*. (See Gairdner 'On Mineral Springs,' p. 404.)

Though unacquainted with the results of employing hot sand or ashes, as done by the Turks, we can conceive them useful in allaying cramps and neuralgic pains, as heat generally does in whatever way applied. A collection of the opinions of ancient writers on the subject was published in the sixteenth century. ('De balneis omnia quæ extant apud Græcos, Latinos, et Arabes,' fol. Venet. apud Junt. 1553.) The best modern treatise is that of Marcard, in German, an abstract of which may be found in Dr. Beddoes's 'Treatise on Consumption.' A French translation of it was published in 1802. The natural baths will be treated of under the article WATERS, MINERAL.
